PyPhysim is a python library implementing functions, classes and simulators related to the physical layer of digital communications systems.

LIST OF DOCUMENTATION ARTICLES

PyPhysim organization is described in [PyPhysim organization](#), where a summary of the several packages in PyPhysim is shown. For instructions on how to implement new simulations with PyPhysim see [Implementing Simulators with PyPhysim](#).

The complete list of articles in the PyPhysim documentation is shown below.

1.1 PyPhysim organization

The PyPhysim library is roughly organized in several packages with related modules. Most of the packages define functions and classes used to write physical layer simulators, but two packages are special: the *apps* package and the *tests* package. The *apps* package contains actual simulators that can be run, while the *tests* package, as the name suggests, have tests for the several packages in PyPhysim.

At last, there is also a *bin* directory containing a few scripts. One useful script to be run while developing PyPhysim is the **run_python_coreage** script, which will run the python-coverage program in all the test files in the tests folder. This will give a good estimate of the test coverage in PyPhysim (see [Writing Unittests for PyPhysim](#) for details about writting unittests for PyPhysim).

1.1.1 Packages in PyPhysim

A summary of the available packages in PyPhysim is shown below.

pyphysim package

Subpackages

pyphysim.c_extensions package

Module contents

Module containing compiled Cython extensions

pyphysim.cell package

Submodules

pyphysim.cell.cell module

Module that implements Cell and Cluster related classes.

class `pyphysim.cell.cell.AccessPoint` (*pos*: `complex`, *ap_id*: `Optional[Union[str, int]] = None`)

Bases: `pyphysim.cell.cell.Node`

Access point class.

An access point acts as a transmitter to one of more users.

Parameters

- **pos** (`complex`) – The central position of the cell in the complex grid.
- **ap_id** (`int`, `str`, `optional`) – The AccessPoint ID. If not provided the access point won't have an ID and its plot will shown a symbol at the access point location instead of the ID.

_plot_common_part (*ax*: `Any`) → `None`

Common code for plotting the classes. Each subclass must implement a *plot* method in which it calls the command to plot the class shape followed by *_plot_common_part*.

Parameters **ax** (*A matplotlib axis*) – The axis where the cell will be plotted.

add_user (*new_user*: `pyphysim.cell.cell.Node`, *relative_pos_bool*: `bool = True`) → `None`

Associate a new user with the access point.

Parameters

- **new_user** (`Node`) – The new user to be associated with the access point.
- **relative_pos_bool** (`bool`) – Indicates it the position of the *new_user* is relative.

delete_all_users () → `None`

Delete all users from the cell.

property num_users

Get method for the num_users property.

Returns The number of users associated with the AccessPoint.

Return type `int`

plot (*ax*: `Optional[Any] = None`) → `None`

Plot the AccessPoint using the matplotlib library.

Parameters **ax** (*A matplotlib axis, optional*) – The axis where the cell will be plotted. If not provided, a new figure (and axis) will be created.

property pos

Get the AccessPoint position.

Returns The AccessPoint position.

Return type `complex`

property users

Get method for the users property.

Returns The users associated with the AccessPoint.

Return type `list[Node]`

```
class pyphysim.cell.cell.Cell (pos: complex, radius: float, cell_id: Optional[Union[str, int]] =  
                                None, rotation: float = 0.0)
```

Bases: `pyphysim.cell.shapes.Hexagon`, `pyphysim.cell.cell.CellBase`

Class representing an hexagon cell.

Parameters

- **pos** (*complex*) – The central position of the cell in the complex grid.
- **radius** (*float*) – The cell radius.
- **cell_id** (*str*, *int*, *optional*) – The cell ID. If not provided the cell won't have an ID and its plot will shown a symbol in cell center instead of the cell ID.
- **rotation** (*float*, *optional*) – The rotation of the cell (regarding the cell center).

```
plot (ax: Optional[Any] = None) → None
```

Plot the cell using the matplotlib library.

If an axes 'ax' is specified, then the shape is added to that axis. Otherwise a new figure and axis are created and the shape is plotted to that.

Parameters **ax** (*A matplotlib axis*, *optional*) – The axis where the cell will be plotted. If not provided, a new figure (and axis) will be created.

```
class pyphysim.cell.cell.Cell3Sec (pos: complex, radius: float, cell_id: Optional[Union[str,  
                                int]] = None, rotation: float = 0.0)
```

Bases: `pyphysim.cell.cell.CellBase`

Class representing a cell with 3 sectors.

Each sector corresponds to an hexagon.

Parameters

- **pos** (*complex*) – The central position of the cell in the complex grid.
- **radius** (*float*) – The cell radius. The sector radius will be equal to half the cell radius.
- **cell_id** (*str*, *int*, *optional*) – The cell ID. If not provided the cell won't have an ID and its plot will shown a symbol in cell center instead of the cell ID.
- **rotation** (*float*, *optional*) – The rotation of the cell (regarding the cell center).

```
_calc_sectors_positions () → numpy.ndarray
```

Calculates the positions of the sectors with the current rotation, center position and radius.

Returns The positions of the 3 sectors.

Return type `np.ndarray`

```
_get_vertex_positions () → numpy.ndarray
```

Calculates the vertex positions ignoring any rotation and considering that the shape is at the origin (rotation and translation will be added automatically later).

Returns **vertex_positions** – The positions of the vertexes of the shape.

Return type `np.ndarray`

```
add_random_user_in_sector (sector: int, user_color: Optional[str] = None, min_dist_ratio:  
                             float = 0.0) → None
```

Adds a user randomly located in the specified *sector* of the cell.

Parameters

- **sector** (*int*) – The sector index. Can only be 1, 2 or 3.
- **user_color** (*str*) – Color of the user's marker.
- **min_dist_ratio** (*float*) – Minimum allowed (relative) distance between the cell center and the generated random user. The value must be between 0 and 0.7.

add_random_users_in_sector (*num_users: int, sector: int, user_color: Optional[str] = None, min_dist_ratio: float = 0.0*) → *None*

Add *num_users* users randomly in the specified *sector* of the cell

Parameters

- **num_users** (*int*) – Number of users to be added to the sector.
- **sector** (*int*) – The sector index. Can only be 1, 2 or 3.
- **user_color** (*str*) – Color of the user's marker.
- **min_dist_ratio** (*float*) – Minimum allowed (relative) distance between the cell center and the generated random user. The value must be between 0 and 0.7.

plot (*ax: Optional[Any] = None*) → *None*

Plot the cell using the matplotlib library.

If an axes 'ax' is specified, then the shape is added to that axis. Otherwise a new figure and axis are created and the shape is plotted to that.

Parameters ax (*A matplotlib axis, optional*) – The axis where the cell will be plotted. If not provided, a new figure (and axis) will be created.

property pos

Get the Cell3Sec position.

Returns The Cell3Sec position.

Return type *complex*

property radius

Get the radius of the Cell3Sec object.

Returns The radius of the Cell3Sec object.

Return type *float*

property rotation

Get method for the rotation property.

Returns The shape rotation.

Return type *float*

property secradius

Get method for the secradius property.

The radius of a sector.

Returns The radius of one sector of the Cell3Sec object.

Return type *float*

class `pyphysim.cell.cell.CellBase` (*pos: complex, radius: float, cell_id: Optional[Union[str, int]] = None, rotation: float = 0.0, **kw*)

Bases: `pyphysim.cell.shapes.Shape`, `pyphysim.cell.cell.AccessPoint`

Base class for all cell types.

A cell is an AccessPoint with a predefined shape, where the users associated with it are inside the shape.

Parameters

- **pos** (*complex*) – The central position of the cell in the complex grid.
- **radius** (*float*) – The cell radius.
- **cell_id** (*str, int, optional*) – The cell ID. If not provided the cell won't have an ID and its plot will shown a symbol in cell center instead of the cell ID.
- **rotation** (*float, optional*) – The rotation of the cell (regarding the cell center).

static _validate_ratio (*ratio: float*) → *float*

Return *ratio* if is valid, 1.0 if *ratio* is None, or throw an exception if it is not valid.

This is a helper method used in the `add_border_user` method implementation.

Parameters **ratio** (*float*) – The ratio (a number between 0 and 1).

Returns **ratio** – The valid ratio. If ratio parameter was 'None' then 1.0 will be returned.

Return type *float*

Raises **ValueError** – If *ratio* is not between 0 and 1.

add_border_user (*angles: Union[float, Iterable[float]], ratio: Optional[Union[float, Iterable[float]]] = None, user_color: Optional[Union[str, Iterable[str]]] = None*) → *None*

Adds a user at the border of the cell, located at a specified angle (in degrees).

If the *angles* variable is an iterable, one user will be added for each value in *angles*. Also, in that case *ratio* and *user_color* may also be iterable with the same length of *angles* in order to specify individual *ratio* and *user_color* for each angle.

Parameters

- **angles** (*float | list[float] | np.ndarray*) – Angle(s) for which users will be added (may be a single number or an iterable).
- **ratio** (*float | list[float] | np.ndarray | None*) – The ration (relative distance from cell center) for which users will be added (may be a single number or an iterable). If not specified the users will be added to the cell's border at the angles specified in *angles*.
- **user_color** (*str | list[str], optional*) – Color of the user's marker.

Raises **ValueError** – If the ratio is invalid (negative or greater than 1).

add_random_user (*user_color: Optional[str] = None, min_dist_ratio: float = 0.0*) → *None*

Adds a user randomly located in the cell.

The variable *user_color* can be any color that the plot command and friends can understand. If not specified the default value of the node class will be used.

Parameters

- **user_color** (*str, optional*) – Color of the user's marker.
- **min_dist_ratio** (*float*) – Minimum allowed (relative) distance between the cell center and the generated random user. The value must be between 0 and 0.7.

add_random_users (*num_users: int, user_color: Optional[str] = None, min_dist_ratio: float = 0.0*) → *None*

Add *num_users* users randomly located in the cell.

Parameters

- **num_users** (*int*) – Number of users to be added to the cell.
- **user_color** (*str*, *optional*) – Color of the user’s marker.
- **min_dist_ratio** (*float*) – Minimum allowed (relative) distance between the cell center and the generated random user. The value must be between 0 and 0.7.

add_user (*new_user*: `pyphysim.cell.cell.Node`, *relative_pos_bool*: *bool* = *True*) → *None*

Adds a new user to the cell.

Parameters

- **new_user** (*Node*) – The new user to be added to the cell.
- **relative_pos_bool** (*bool*, *optional* (default to *True*)) – Indicates if the ‘pos’ attribute of the *new_user* is relative to the center of the cell or not.

Returns

Return type *None*

Raises **ValueError** – If the user position is outside the cell (the user won’t be added).

plot_border (*ax*: *Optional*[*Any*] = *None*) → *None*

Plot the border of the cell.

If an axes ‘ax’ is specified, then the shape is added to that axis. Otherwise a new figure and axis are created and the shape is plotted to that.

Parameters *ax* (*A matplotlib axis*, *optional*) – The axis where the cell will be plotted. If not provided, a new figure (and axis) will be created.

class `pyphysim.cell.cell.CellSquare` (*pos*: *complex*, *side_length*: *float*, *cell_id*: *Optional*[*Union*[*str*, *int*]] = *None*, *rotation*: *float* = 0.0)

Bases: `pyphysim.cell.shapes.Rectangle`, `pyphysim.cell.cell.CellBase`

Class representing a ‘square’ cell.

Parameters

- **pos** (*complex*) – The central position of the cell in the complex grid.
- **side_length** (*float*) – The cell side length.
- **cell_id** (*str*, *int*, *optional*) – The cell ID. If not provided the cell won’t have an ID and its plot will shown a symbol in cell center instead of the cell ID.
- **rotation** (*float*, *optional*) – The rotation of the cell (regarding the cell center).

add_user (*new_user*: `pyphysim.cell.cell.Node`, *relative_pos_bool*: *bool* = *True*) → *None*

Adds a new user to the cell.

Parameters

- **new_user** (*Node*) – The new user to be added to the cell.
- **relative_pos_bool** (*bool*, *optional*) – Indicates if the ‘pos’ attribute of the *new_user* is relative to the center of the cell or not.

Raises **ValueError** – If the user position is outside the cell (the user won’t be added).

plot (*ax*: *Optional*[*Any*] = *None*) → *None*

Plot the cell using the matplotlib library.

If an axes ‘ax’ is specified, then the shape is added to that axis. Otherwise a new figure and axis are created and the shape is plotted to that.

Parameters **ax** (*A matplotlib axis, optional*) – The axis where the cell will be plotted. If not provided, a new figure (and axis) will be created.

class `pyphysim.cell.cell.CellWrap` (*pos: complex, wrapped_cell: pyphysim.cell.cell.CellBase, include_users_bool: bool = False*)

Bases: `pyphysim.cell.cell.CellBase`

Class that wraps another cell.

Parameters

- **pos** (*complex*) – The central position where the wrapped cell will be in the complex grid.
- **wrapped_cell** (*T <= CellBase*) – The wrapped cell. It must be an object of some subclass of CellBase.
- **include_users_bool** (*bool*) – Set to True if the users of the original cells should appear in the wrapped version.

__get_vertex_positions () → `numpy.ndarray`

Calculates the vertex positions ignoring any rotation and considering that the shape is at the origin (rotation and translation will be added automatically later).

Returns **vertex_positions** – The positions of the vertexes of the shape.

Return type `np.ndarray`

property **num_users**

Get method for the num_users property.

Returns The number of users associated with the AccessPoint.

Return type `int`

plot (*ax: Optional[Any] = None*) → `None`

Plot the shape using the matplotlib library.

Parameters **ax** (*A matplotlib ax, optional*) – The ax where the shape will be plotted. If not provided, a new figure (and ax) will be created.

Notes

If an axes ‘ax’ is specified, then the shape is added to that axes. Otherwise a new figure and axes are created and the shape is plotted to that.

property **radius**

Get the radius of the CellWrap object.

Returns The radius of the CellWrap object.

Return type `float`

property **rotation**

Get the rotation of the CellWrap object.

Returns The rotation of the CellWrap object.

Return type `float`

property **users**

Get method for the users property.

Returns The users associated with the AccessPoint.

Return type `list`

```
class pyphysim.cell.cell.Cluster (cell_radius: float, num_cells: int, pos: complex = 0j, cluster_id: Optional[int] = None, cell_type: str = 'simple', rotation: float = 0.0)
```

Bases: `pyphysim.cell.shapes.Shape`

Class representing a cluster of Hexagonal cells.

Valid cluster sizes are given by the formula $N = i^2 + i * j + j^2$ where i and j are integer numbers. The allowed values in the Cluster class are summarized below with the corresponding values of i and j.

| i, j | N |
|------|----|
| 1,0 | 01 |
| 1,1 | 03 |
| 2,0 | 04 |
| 2,1 | 07 |
| 3,1 | 13 |
| 3,2 | 19 |

Parameters

- **cell_radius** (float) – Radius of the cells in the cluster.
- **num_cells** (int) – Number of cells in the cluster.
- **pos** (complex) – Central Position of the Cluster in the complex grid.
- **cluster_id** (int) – ID of the cluster.
- **cell_type** (str) – The type of the cell as a string. It can be either 'simple', '3sec' or 'square'. If it is 'simple' it means the standard hexagon shaped cell. If '3sec' it means a 3 sectorized cell composed of 3 hexagons.
- **rotation** (float) – Rotation of the cluster.

```
static _calc_cell_height (radius: float) → float
```

Calculates the cell height from the cell radius.

Parameters **radius** (float) – The cell Radius.

Returns **height** – The cell height.

Return type float

```
static _calc_cell_positions (cell_radius: float, num_cells: int, cell_type: str = 'simple', rotation: Optional[float] = None) → numpy.ndarray
```

Helper function used by the Cluster class.

The calc_cell_positions method calculates the position (and rotation) of the 'num_cells' different cells, each with radius equal to 'cell_radius', so that they properly fit in the cluster.

Parameters

- **cell_radius** (float) – Radius of each cell in the cluster.
- **num_cells** (int) – Number of cells in the cluster.
- **cell_type** (str) – The type of the cell. It should be a string with one of the possible values: 'simple', '3sec', or 'square'. If it is 'simple' it means the standard hexagon shaped cell. If '3sec' it means a 3 sectorized cell composed of 3 hexagons.
- **rotation** (float | None, optional) – Rotation of the cluster.

Returns `cell_positions` – The first column of `cell_positions` has the positions of the cells in a cluster with `num_cells` cells with radius `cell_radius`. The second column has the rotation of each cell.

Return type `np.ndarray`

static `_calc_cell_positions_3sec` (`cell_radius: float`, `num_cells: int`, `rotation: Optional[float] = None`) → `numpy.ndarray`

Helper function used by the Cluster class.

The `_calc_cell_positions_3sec` method calculates the position (and rotation) of the ‘num_cells’ different cells, each with radius equal to ‘cell_radius’, so that they properly fit in the cluster.

Parameters

- **cell_radius** (`float`) – Radius of each cell in the cluster.
- **num_cells** (`int`) – Number of cells in the cluster.
- **rotation** (`float | None, optional`) – Rotation of the cluster.

Returns `cell_positions` – The first column of `cell_positions` has the positions of the cells in a cluster with `num_cells` cells with radius `cell_radius`. The second column has the rotation of each cell.

Return type `np.ndarray`

static `_calc_cell_positions_hexagon` (`cell_radius: float`, `num_cells: int`, `rotation: Optional[float] = None`) → `numpy.ndarray`

Helper function used by the Cluster class.

The `calc_cell_positions` method calculates the position (and rotation) of the ‘num_cells’ different cells, each with radius equal to ‘cell_radius’, so that they properly fit in the cluster.

Parameters

- **cell_radius** (`float`) – Radius of each cell in the cluster.
- **num_cells** (`int`) – Number of cells in the cluster.
- **rotation** (`float | None, optional`) – Rotation of the cluster.

Returns The first column of `cell_positions` has the positions of the cells in a cluster with `num_cells` cells with radius `cell_radius`. The second column has the rotation of each cell.

Return type `np.ndarray`

static `_calc_cell_positions_square` (`side_length: float`, `num_cells: int`, `rotation: Optional[float] = None`) → `numpy.ndarray`

Helper function used by the Cluster class.

The `calc_cell_positions` method calculates the position (and rotation) of the ‘num_cells’ different cells, each with side equal to ‘cell_radius’, so that they properly fit in the cluster.

Parameters

- **side_length** (`float`) – The side length of each square cell in the cluster.
- **num_cells** (`int`) – Number of cells in the cluster.
- **rotation** (`float | None, optional`) – Rotation of the cluster.

Returns `cell_positions` – The first column of `cell_positions` has the positions of the cells in a cluster with `num_cells` cells with radius `cell_radius`. The second column has the rotation of each cell.

Return type `np.ndarray`

`_calc_cluster_external_radius()` \rightarrow `float`

Calculates the cluster external radius.

The cluster external radius is equal to the radius of the smallest circle (located at the center of the cluster) that contains the cluster. This circle should touch only the most external vertexes of the cells in the cluster.

Get the vertex positions of the last cell.

Returns `external_radius` – The cluster external radius.

Return type `float`

`static _calc_cluster_radius(num_cells: int, cell_radius: float)` \rightarrow `float`

Calculates the “cluster radius” for a cluster with “num_cells” cells, each cell with radius equal to “cell_radius”. The cluster “radius” is equivalent to half the distance between two clusters when they are in a Grid.

Parameters

- **`num_cells`** (`int`) – Number of cells in the cluster.
- **`cell_radius`** (`float`) – Radius of each cell in the cluster.

Returns `cluster_radius` – The radius of a cluster with `num_cells` cells with radius `cell_radius`.

Return type `float`

Notes

The cluster “radius” is equivalent to half the distance between two clusters.

`static _get_ii_and_jj(num_cells: int)` \rightarrow `Tuple[int, int]`

Valid cluster sizes are given by the formula

$$N = i^2 + i * j + j^2$$

where `i` and `j` are integer numbers and “N” is the number of cells in the cluster. This static function returns the values “i” and “j” for a given “N”. The values are summarized below.

| i, j | N |
|------|----|
| 1,0 | 01 |
| 1,1 | 03 |
| 2,0 | 04 |
| 2,1 | 07 |
| 3,1 | 13 |
| 3,2 | 19 |

Parameters **`num_cells`** (`int`) – Number of cells in the cluster.

Returns `ii` and `jj` – The `ii` and `jj` values corresponding to number of cells ‘num_cells’.

Return type (`int,int`)

Notes

If `num_cells` is not in the table above then (0, 0) will be returned.

`_get_outer_vertexes` (*vertexes*: `numpy.ndarray`, *central_pos*: `complex`, *distance*: `float`) → `numpy.ndarray`

Filter out vertexes closer to the shape center than *distance*.

This is a helper method used in the `_get_vertex_positions` method.

Parameters

- **vertexes** (`np.ndarray`) – The outer vertexes of the cluster.
- **central_pos** (`complex`) – Central position of the shape.
- **distance** (`float`) – A minimum distance. Any vertex that is closer to the shape center than this distance will be removed.

Returns `outer_vertexes` – The cluster outer vertexes.

Return type `np.ndarray`

`_get_vertex_positions` () → `numpy.ndarray`

Get the vertex positions of the cluster borders.

Returns `vertex_positions` – The vertex positions of the cluster borders.

Return type `np.ndarray`

Notes

This is only valid for cluster sizes from 1 to 19.

`_ii_and_jj` = {1: (1, 0), 3: (1, 1), 4: (2, 0), 7: (2, 1), 13: (3, 1), 19: (3, 2)}

`_normalized_cell_positions`: `Dict[int, numpy.ndarray] = {}`

`add_border_users` (*cell_ids*: `Union[Iterable[int], int]`, *angles*: `Union[Iterable[float], float]`, *ratios*: `Union[Iterable[float], float] = 1.0`, *user_color*: `Optional[Union[str, Iterable[str]]] = None`) → `None`

Add users to all the cells indicated by *cell_indexes* at the specified angle(s) (in degrees) and ratio (relative distance from the center to the border of the cell).

Parameters

- **cell_ids** (`int` | `list[int]` | `np.ndarray`) – IDs of the cells in the Cluster for which users will be added. The first cell has an ID equal to 1 and *cell_ids* may be an iterable with the IDs of several cells.
- **angles** (`float` | `list[float]` | `np.ndarray`) – Angles (in degrees)
- **ratios** (`float` | `list[float]`) – Ratios (from 0 to 1)
- **user_color** (`str` | `list[str]`) – Color of the user's marker.

Examples

```
>>> cluster = Cluster(cell_radius=1.0, num_cells=3)
>>> # Add a single user in the angle of 30 degrees with a ration of
>>> # 0.9 to the first cell in the cluster
>>> cluster.add_border_users(1, 30, 0.9)
>>>
>>> # Add 3 users at the angles of 0, 95 and 185 degrees to the
>>> # second cell of the cluster
>>> cluster.add_border_users(2, [0, 95, 185], 0.9, 'b')
>>>
>>> # Add one user in each cell at the angle of 10 degrees
>>> cluster.add_border_users([1, 2, 3], 10, 0.9, 'g')
>>>
>>> # Add a user in each cell at different angles per cell
>>> cluster.add_border_users([1, 2, 3], [90, 150, 190], 0.9, 'y')
>>>
>>> # Add multiple users to multiple cells at different angles
>>> cluster.add_border_users([1, 2, 3], [[180, 270], [-30],
↵[60, 120]], 0.9, 'k')
```

add_random_users (*cell_ids*: *Optional[Union[Iterable[int], int]] = None*, *num_users*: *Union[Iterable[int], int] = 1*, *user_color*: *Optional[Union[str, Iterable[str]]] = None*, *min_dist_ratio*: *Union[Iterable[float], float] = 0.0*) → *None*

Adds one or more users to the Cells with the specified cell IDs (the first cell has an ID equal to 1.).

Parameters

- **cell_ids** (*int | list[int] | np.ndarray*) – IDs of the cells in the Cluster for which users will be added. The first cell has an ID equal to 1 and *cell_ids* may be an iterable with the IDs of several cells. If not provided, all cells will be assumed.
- **num_users** (*int | list[int] | np.ndarray*) – Number of users to be added to each cell.
- **user_color** (*str | list[str], optional*) – Color of the user's marker.
- **min_dist_ratio** (*float, list[float], optional*) – Minimum allowed (relative) distance between the cell center and the generated random user. See `Cell.add_random_user` method for details.

Notes

If *cell_ids* is an iterable then the other attributes (*num_users*, *user_color* and *min_dist_ratio*) may also be iterable with the same length of *cell_ids* in order to specifying individual values for each cell ID.

calc_dist_all_users_to_each_cell () → *numpy.ndarray*

Returns a matrix with the distance from each user to each cell center.

This matrix is suitable to later calculate the path loss from each base station to each mobile station.

Because usually the base station is the transmitter and the mobile station is the receiver the matrix is such that each column corresponds to a different base station and each row corresponds to a different mobile station.

Returns *all_dists* – Distance from each cell center to each user.

Return type *np.ndarray*

Notes

There is no explicit indication from which cell each user came from. However, in a case, for instance, where there are 3 cells in the cluster with 2, 2 and 3 users in each of them, respectively, then the first 2 rows correspond to the users in the first cell, the following 2 rows correspond to the users in the second cell and the last three rows correspond to the users in the third cell.

calc_dist_all_users_to_each_cell_no_wrap_around() → `numpy.ndarray`

Returns a matrix with the distance from each user to each cell center.

This matrix is suitable to later calculate the path loss from each base station to each mobile station.

Because usually the base station is the transmitter and the mobile station is the receiver the matrix is such that each column corresponds to a different base station and each row corresponds to a different mobile station.

Returns `all_dists` – Distance from each cell center to each user.

Return type `np.ndarray`

Notes

There is no explicit indication from which cell each user came from. However, in a case, for instance, where there are 3 cells in the cluster with 2, 2 and 3 users in each of them, respectively, then the first 2 rows correspond to the users in the first cell, the following 2 rows correspond to the users in the second cell and the last three rows correspond to the users in the third cell.

calc_dists_between_cells() → `numpy.ndarray`

This method calculates the distance between any two cells in the cluster possibly considering wrap around.

If the `create_wrap_around_cells` method was called before this one, then when calculating the distance between two cells if the distance between a given cell and the wrapped version of another cell is smaller then the distance to that other cell it will be used instead.

For instance, the

Returns `dists` – A matrix with the distance from each cell to each other cell in the cluster.

Return type `np.ndarray`

property cell_height

Get method for the `cell_height` property.

Returns The height of the cells in the Cluster.

Return type `float`

property cell_id_fontsize

Get method for the `cell_id_fontsize` property.

The value of `cell_id_fontsize` only matters for plotting the cluster.

Returns The font size that should be used for the cell IDs in the plot.

Return type `int | None`

property cell_radius

Get method for the `cell_radius` property.

Returns The radius of the cells in the Cluster.

Return type `float`

create_wrap_around_cells (*include_users_bool*: *bool* = *False*) → *None*

This function will create the wrapped cells, as well as the wrap info data.

Parameters *include_users_bool* (*bool*) – Set to True if the users of the original cells should appear in the wrapped version.

delete_all_users (*cell_id*: *Optional[Union[Iterable[int], int]]* = *None*) → *None*

Remove all users from one or more cells.

If *cell_id* is an integer > 0, only the users from the cell whose index is *cell_id* will be removed. If *cell_id* is an iterable, then the users of cells pointed by it will be removed. If *cell_id* is *None* or not specified, then the users of all cells will be removed.

Parameters *cell_id* (*int* | *list[int]*, *optional*) – ID(s) of the cells from which users will be removed. If equal to *None*, all the users from all cells will be removed.

property external_radius

Get the *external_radius* of the Cluster.

Returns The *external_radius* of the Cluster.

Return type *float*

get_all_users () → *List[pyphysim.cell.cell.Node]*

Return all users in the cluster.

Returns *all_users* – A list with all users in the cluster.

Return type *list[Node]*

get_cell_by_id (*cell_id*: *int*) → *pyphysim.cell.cell.CellBase*

Get the cell in the Cluster with the given *cell_id*.

Parameters *cell_id* (*int*) – The ID of the desired cell.

Returns *c* – The desired cell.

Return type *Cell*

property num_cells

Get method for the *num_cells* property.

Returns Number of cells in the Cluster.

Return type *int*

property num_users

Get method for the *num_users* property.

Returns The number of users in the Cluster.

Return type *int*

plot (*ax*: *Optional[Any]* = *None*) → *None*

Plot the cluster.

Parameters *ax* (*A matplotlib axis*, *optional*) – The axis where the cluster will be plotted. If not provided, a new figure (and axis) will be created.

plot_border (*ax*: *Optional[Any]* = *None*) → *None*

Plot only the border of the Cluster.

Only work's for cluster sizes that can calculate the cluster vertices, such as cluster with 1, 7 or 19 cells.

Parameters *ax* (*A matplotlib axis*, *optional*) – The axis where the cluster will be plotted. If not provided, a new figure (and axis) will be created.

property pos

Get the Cluster position.

Returns The Cluster position.

Return type `complex`

property radius

Get the radius of the Cluster object.

Returns The radius of the Cluster object.

Return type `float`

property rotation

Get method for the rotation property.

Returns The shape rotation.

Return type `float`

property vertices

Get the vertex positions of the cluster borders.

Returns `vertex_positions` – The vertex positions of the cluster borders.

Return type `np.ndarray`

Notes

This is only valid for cluster sizes from 1 to 19.

class `pyphysim.cell.cell.Grid`

Bases: `object`

Class representing a grid of clusters of cells or a single cluster with its surrounding cells.

Valid cluster sizes are given by the formula $N = i^2 + i * j + j^2$ where i and j are integer numbers. The values allowed in the Cluster are summarized below with the corresponding values of i and j.

| i, j | N |
|------|----|
| 1,0 | 01 |
| 1,1 | 03 |
| 2,0 | 04 |
| 2,1 | 07 |
| 3,1 | 13 |
| 3,2 | 19 |

`_calc_cluster_pos2()` → `complex`

Calculates the central position of clusters with 2 cells.

Returns `central_pos` – Central position of the next cluster to be added to the Grid.

Return type `complex`

Notes

The returned central position will depend on how many clusters were already added to the grid.

`_calc_cluster_pos3()` → `complex`

Calculates the central position of clusters with 3 cells.

Returns `central_pos` – Central position of the next cluster to be added to the Grid.

Return type `complex`

Notes

The returned central position will depend on how many clusters were already added to the grid.

`_calc_cluster_pos7()` → `complex`

Calculates the central position of clusters with 7 cells.

Returns `central_pos` – Central position of the next cluster to be added to the Grid.

Return type `complex`

Notes

The returned central position will depend on how many clusters were already added to the grid.

`_colors = ['b', 'g', 'r', 'c', 'm', 'y', 'k', 'w']`

`_repr_png_()` → Any

Return the PNG representation of the shape.

`_repr_some_format_ (extension: str = 'png', axis_option: str = 'equal') → Any`

Return the representation of the shape in the desired format.

Parameters

- **extension** (`str`) – The extension of the desired format. This should be something that the savefig method in a matplotlib figure can understand, such as 'png', 'svg', etc.
- **axis_option** (`str`) – Option to be given to the ax.axis function.

Returns The representation in the desired format.

Return type Any

`_repr_svg_()` → Any

Return the SVG representation of the shape.

`clear()` → `None`

Clear everything in the grid.

`create_clusters (num_clusters: int, num_cells: int, cell_radius: float) → None`

Create the clusters in the grid.

Parameters

- **num_clusters** (`int`) – Number of clusters to be created in the grid.
- **num_cells** (`int`) – Number of cells per clusters.
- **cell_radius** (`float`) – The radius of each cell.

get_cluster_from_index (*index: int*) → *pyphysim.cell.cell.Cluster*

Return the cluster object with index *index* in the Grid.

Parameters *index* (*int*) – The index of the desirable cluster.

Returns The desired cluster in the Grid.

Return type *Cluster*

property num_clusters

Get method for the num_clusters property.

Returns The number of clusters in teh grid.

Return type *int*

plot (*ax: Optional[Any] = None*) → *None*

Plot the grid of clusters.

Parameters *ax* (*A matplotlib axis, optional*) – The axis where the grid will be plotted. If not provided, a new figure (and axis) will be created.

class *pyphysim.cell.cell.Node* (*pos: complex, plot_marker: str = '*', marker_color: str = 'r', cell_id: Optional[Union[str, int]] = None, parent_pos: Optional[complex] = None*)

Bases: *pyphysim.cell.shapes.Coordinate*

Class representing a node in the network.

Parameters

- **pos** (*complex*) – The position of the node in the complex grid.
- **plot_marker** (*str*) – The marker to be used in a plot to represent the Node. This marker should be something that matplotlib can understand, such as '*', for instance.
- **marker_color** (*str*) – The color that will be used to plot the marker representing the Node. This color should be something that matplotlib can understand, such as 'r' for the color red, for instance.
- **cell_id** (*str, int, optional*) – The ID of the cell where the Node is located.
- **parent_pos** (*complex*) – The position of the cell where the Node is located (if any).

plot_node (*ax: Optional[Any] = None*) → *None*

Plot the node using the matplotlib library.

If an axes 'ax' is specified, then the node is added to that axes. Otherwise a new figure and axes are created and the node is plotted to that.

Parameters *ax* (*A matplotlib axis, optional*) – The axis where the node will be plotted. If not provided, a new figure (and axis) will be created.

property relative_pos

Get method for the relative_pos property.

Returns The relative position of the Node regarding its parent Node's position.

Return type *complex | None*

pyphysim.cell.shapes module

Module implementing geometric shapes.

Each shape knows how to plot itself.

class `pyphysim.cell.shapes.Circle` (*pos: complex, radius: float*)

Bases: `pyphysim.cell.shapes.Shape`

Circle shape class.

A circle is initialized only from a coordinate and a radius.

Parameters

- **pos** (*complex*) – Coordinate of the center of the circle.
- **radius** (*float*) – Circle's radius.

`_get_vertex_positions` () → *numpy.ndarray*

Calculates the vertex positions considering that the circle is at the origin (translation will be added automatically later).

Returns **vertex_positions** – The positions of the vertexes of the shape.

Return type *np.ndarray*

Notes

It does not make much sense to get the vertexes of a circle, since a circle 'has' infinite vertexes. However, for consistence with the Shape's class interface the `_get_vertex_positions` is implemented such that it returns a subset of the circle vertexes. The number of returned vertexes was arbitrarily chosen as 12.

get_border_point (*angle: float, ratio: Optional[float] = None*) → *complex*

Calculates the coordinate of the point that intercepts the border of the circle if we go from the origin with a given angle (in degrees).

Parameters

- **angle** (*float*) – Angle in degrees
- **ratio** (*float*) – The ratio from the cell center to the border where the desired point is located. It must be a value between 0 and 1.

Returns **point** – A point in the line between the circle's center and the circle's border with the desired angle. If ratio is equal to one the point will be in the end of the line (touching the circle's border)

Return type *complex*

is_point_inside_shape (*point: complex*) → *bool*

Test is a point is inside the circle

Parameters **point** – A single complex number.

Returns True if *point* is inside the circle, False otherwise.

Return type *inside_or_not*

plot (*ax: Any = None*) → *None*

Plot the circle using the Matplotlib library.

Parameters **ax** (*A matplotlib axis, optional*) – The axis where the shape will be plotted. If not provided, a new figure (and axis) will be created.

Notes

If an axes 'ax' is specified, then the shape is added to that axes. Otherwise a new figure and axes are created and the shape is plotted to that.

class `pyphysim.cell.shapes.Coordinate` (*pos: complex*)

Bases: `object`

Base class for a coordinate in a 2D grid.

A Coordinate object knows its location in the grid (represented as a complex number) and how to calculate the distance from it to another location.

calc_dist (*other: pyphysim.cell.shapes.Coordinate*) → `float`

Calculates the distance to another coordinate.

Parameters *other* (`Coordinate`) – A different coordinate object.

Returns *dist* – Distance from self to the other coordinate.

Return type `float`

move_by_relative_coordinate (*rel_pos: complex*) → `None`

Move from the current position to the relative coordinate.

This is equivalent to moving to a new position given by the current position plus *coordinate*.

Parameters *rel_pos* (`complex`) – Relative coordinate

move_by_relative_polar_coordinate (*radius: float, angle: float*) → `None`

Move from the current position to the relative coordinate.

This is equivalent to moving to a new position given by the current position plus a the provided coordinate.

Parameters

- **radius** (`float`) – Distance of the movement in the direction given by *angle*.
- **angle** (`float`) – Angle (in radians) pointing the direction of the movement.

property pos

Get the coordinate position as a complex number.

Returns The coordinate position (a complex number).

Return type `complex`

class `pyphysim.cell.shapes.Hexagon` (*pos: complex, radius: float, rotation: float = 0, **kw*)

Bases: `pyphysim.cell.shapes.Shape`

Hexagon shape class.

Besides the *pos*, *radius* and *rotation* properties from the Shape base class, the Hexagon also has a height property (read-only) from the base of the Hexagon to its center.

Parameters

- **pos** (`complex`) – Coordinate of the shape in the complex grid.
- **radius** (`float`) – Radius of the hexagon. It must be a positive number.
- **rotation** (`float`) – Rotation of the hexagon in degrees.

_get_vertex_positions () → `numpy.ndarray`

Calculates the vertex positions ignoring any rotation and considering that the hexagon is at the origin (rotation and translation will be added automatically later).

Returns `vertex_positions` – The positions of the vertexes of the shape.

Return type `np.ndarray`

property `height`

Get method for the height property.

Returns The height of the Hexagon.

Return type `float`

class `pyphysim.cell.shapes.Rectangle` (*first: `complex`, second: `complex`, rotation: `float` = 0, **kw*)

Bases: `pyphysim.cell.shapes.Shape`

Rectangle shape class.

The rectangle is initialized from two coordinates as well as from the rotation.

Parameters

- **first** (`complex`) – First coordinate (without rotation).
- **second** (`complex`) – Second coordinate (without rotation).
- **rotation** (`float`) – Rotation of the rectangle in degrees.

`_get_vertex_positions()` → `numpy.ndarray`

Calculates the vertex positions ignoring any rotation and considering that the rectangle is at the origin (rotation and translation will be added automatically later).

Returns `vertex_positions` – The positions of the vertexes of the shape.

Return type `np.ndarray`

`_repr_some_format()` (*extension: `str` = 'png', axis_option: `str` = 'tight'*) → Any

Return the representation of the shape in the desired format.

Parameters

- **extension** (`str`) – The extension of the desired format. This should be something that the `savefig` method in a matplotlib figure can understand, such as 'png', 'svg', etc.
- **axis_option** (`str`) – Option to be given to the `ax.axis` function.

Notes

We only subclass the `_repr_some_format_` method from the `Shape` class here so that we can change the `axis_option` to 'tight' (default in the `Shape` class is 'equal').

`is_point_inside_shape()` (*point: `complex`*) → `bool`

Test is a point is inside the rectangle

Parameters `point` (`complex`) – A single complex number.

Returns True if `point` is inside the rectangle, False otherwise.

Return type `bool`

class `pyphysim.cell.shapes.Shape` (*pos: `complex`, radius: `float`, rotation: `float` = 0, **kw*)

Bases: `pyphysim.cell.shapes.Coordinate`

Base class for all 2D shapes.

Each subclass must implement the `_get_vertex_positions` method.

Parameters

- **pos** (*complex*) – Coordinate of the shape in the complex grid.
- **radius** (*float*) – Radius of the shape. It must be positive.
- **rotation** (*float*) – Rotation of the shape in degrees.

abstract `_get_vertex_positions()` → *numpy.ndarray*

Calculates the vertex positions ignoring any rotation and considering that the shape is at the origin (rotation and translation will be added automatically later).

Returns `vertex_positions` – The positions of the vertexes of the shape (as a 1D numpy array).

Return type `np.ndarray`

Notes

Not implemented. Must be implemented in a subclass and return a one-dimensional numpy array (complex dtype) with the vertex positions.

`_repr_png_()` → Any

Return the PNG representation of the shape.

`_repr_some_format_()` (*extension: str = 'png', axis_option: str = 'equal'*) → Any

Return the representation of the shape in the desired format.

Parameters

- **extension** (*str*) – The extension of the desired format. This should be something that the savefig method in a matplotlib figure can understand, such as 'png', 'svg', etc.
- **axis_option** (*str*) – Option to be given to the ax.axis function.

Returns

Return type `output`

`_repr_svg_()` → Any

Return the SVG representation of the shape.

static `calc_rotated_pos()` (*cur_pos: ComplexOrArray, angle: float*) → *ComplexOrArray*

Rotate the complex numbers in the *cur_pos* array by *angle* (in degrees) around the origin.

Parameters

- **cur_pos** (*complex | np.ndarray*) – The complex number(s) to be rotated.
- **angle** (*float*) – Angle in degrees to rotate the positions.

Returns `rotated_pos` – The rotate complex number(s).

Return type `complex | np.ndarray`

get_border_point (*angle: float, ratio: Optional[float] = None*) → *complex*

Calculates the coordinate of the point that intercepts the border of the shape if we go from the origin with a given angle (in degrees).

Parameters

- **angle** (*float*) – Angle in degrees.
- **ratio** (*float*) – The ratio from the cell center to the border where the desired point is located. This MUST be a value between 0 and 1.

Returns **point** – A point in the line between the shape’s center and the shape’s border with the desired angle. If ratio is equal to one the point will be in the end of the line (touching the shape’s border)

Return type `complex`

is_point_inside_shape (*point: complex*) → `bool`

Test is a point is inside the shape.

Parameters **point** – A single complex number.

Returns True if *point* is inside the shape, False otherwise.

Return type `inside_or_not`

plot (*ax: Any = None*) → `None`

Plot the shape using the matplotlib library.

Parameters **ax** (*A matplotlib ax, optional*) – The ax where the shape will be plotted. If not provided, a new figure (and ax) will be created.

Notes

If an axes ‘ax’ is specified, then the shape is added to that axes. Otherwise a new figure and axes are created and the shape is plotted to that.

property radius

Get method for the radius property.

Returns The Shape radius.

Return type `float`

property rotation

Get method for the rotation property.

Returns The shape rotation.

Return type `float`

property vertices

Get method for the vertices property.

Returns The shape vertexes.

Return type `np.ndarray`

property vertices_no_trans_no_rotation

Get the shape vertexes without translation and rotation.

Returns **vertex_positions** – The positions of the vertexes of the shape without any translation or rotation (as a 1D numpy array).

Return type `np.ndarray`

Module contents

Package with cell and shapes related modules.

pyphysim.channels package

Submodules

pyphysim.channels.antennagain module

class pyphysim.channels.antennagain.**AntGainBS3GPP25996** (*number_of_sectors: int = 3*)

Bases: `pyphysim.channels.antennagain.AntGainBase`

Class for antenna model defined by 3GPP in the 25996 norm for sectorized Base Stations.

The antenna gain (in dBi) will depend on the number of sectors of the Base Station.

NOTE: The antenna pattern here is targeted for diversity-oriented implementations (i.e. large inter-element spacings). For beamforming applications that require small spacings, alternative antenna designs may have to be considered leading to a different antenna pattern.

Parameters **number_of_sectors** (*int*) – The number of sectors of the base station. It can be either 3 or 6.

get_antenna_gain (*angle: NumberOrArray*) → *NumberOrArray*

Get the antenna gain for the given angle.

Parameters **angle** (*float | np.ndarray*) – Angle between the direction of interest and the boresight of the antenna. This can also be a numpy array with angles.

Returns The gain (in linear scale) for the provided angle.

Return type *float | np.ndarray*

class pyphysim.channels.antennagain.**AntGainBase**

Bases: `object`

Base class for antenna models.

get_antenna_gain (*angle: NumberOrArray*) → *NumberOrArray*

Get the antenna gain for the given angle.

Parameters **angle** (*float | np.ndarray*) – Angle between the direction of interest and the boresight of the antenna. This can also be a numpy array with angles.

Returns The gain (in linear scale) for the provided angle.

Return type *float | np.ndarray*

class pyphysim.channels.antennagain.**AntGainOmni** (*ant_gain: Optional[float] = None*)

Bases: `pyphysim.channels.antennagain.AntGainBase`

Class for Omnidirectional antenna gain model.

Parameters **ant_gain** (*float, optional*) – The antenna gain (in dBi). If not provided then 0dBi will be assumed.

get_antenna_gain (*angle: NumberOrArray*) → *NumberOrArray*

Get the antenna gain for the given angle.

Parameters **angle** (*float* | *np.ndarray*) – Angle between the direction of interest and the boresight of the antenna. This can also be a numpy array with angles.

Returns The gain (in linear scale) for the provided angle.

Return type *float* | *np.ndarray*

pyphysim.channels.fading module

```
class pyphysim.channels.fading.TdlChannel (fading_generator:
                                         Union[pyphysim.channels.fading_generators.JakesSampleGenerator,
                                         pyphysim.channels.fading_generators.RayleighSampleGenerator],
                                         channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile]
                                         = None, tap_powers_dB: Optional[numpy.ndarray] = None, tap_delays:
                                         Optional[numpy.ndarray] = None, Ts: Optional[float] = None)
```

Bases: *object*

Tapped Delay Line channel model, which corresponds to a multipath channel.

You can create a new TdlChannel object either specifying the channel profile or specifying both the channel tap powers and delays.

Parameters

- **fading_generator** (*FadingGenerator*) – The instance of a fading generator in the *fading_generators* module. It should be a subclass of *FadingSampleGenerator*. The fading generator will be used to generate the channel samples. If the shape of the *fading_generator* is not *None*, then it must contain two positive integers, and a MIMO transmission will be employed, where the first integer in shape corresponds to the number of receive antennas while the second integer corresponds to the number of transmit antennas
- **channel_profile** (*TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- **tap_powers_dB** (*np.ndarray*) – The powers of each tap (in dB). Dimension: $L \times 1$
Note: The power of each tap will be a negative number (in dB).
- **tap_delays** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: $L \times 1$

```
_TdlChannel_prepare_transmit_signal_shape (signal: numpy.ndarray) → numpy.ndarray
```

Helper method called in *corrupt_data* and *corrupt_data_in_freq_domain* methods to prepare the shape of transmit *signal*.

If there is only one transmit antenna but signal is 1D, then an extra dimension will be added to *signal*. Otherwise the *signal* will be just returned.

Parameters **signal** (*np.ndarray*) – The signal to be transmitted. This should be 1D for SISO systems (or SIMO systems) and 2D for MIMO systems.

Returns Either the same signal of signal with an added dimension.

Return type *np.ndarray*

```
_set_fading_generator_shape (new_shape: Optional[Tuple[int, ...]]) → None
```

Set the shape of the fading generator.

Parameters `new_shape` (`tuple[int]`, `None`) – The new shape of the fading generator.
 Note that the actual shape will be set to (self.num_taps, new_shape)

property channel_profile

Return the channel profile.

Returns The channel profile.

Return type `TdlChannelProfile`

corrupt_data (`signal`: `numpy.ndarray`) → `numpy.ndarray`

Transmit the signal through the TDL channel.

Parameters `signal` (`np.ndarray`) – The signal to be transmitted. This should be 1D for SISO systems (or SIMO systems) and 2D for MIMO systems.

Returns The received signal after transmission through the TDL channel

Return type `np.ndarray`

corrupt_data_in_freq_domain (`signal`: `numpy.ndarray`, `fft_size`: `int`, `carrier_indexes`: `Optional[Union[numpy.ndarray, List[int], slice]] = None`) → `numpy.ndarray`

Transmit the signal through the TDL channel, but in the frequency domain.

This is ROUGHLY equivalent to modulating `signal` with OFDM using `fft_size` subcarriers, transmitting through a regular `TdlChannel`, and then demodulating with OFDM to recover the received signal.

One important difference is that here the channel is considered constant during the transmission of `fft_size` elements in `signal`, and then it is varied by the equivalent of the variation for that number of elements. That is, the channel is block static.

Parameters

- **signal** (`np.ndarray`) – The signal to be transmitted. This should be 1D for SISO systems (or SIMO systems) and 2D for MIMO systems.
- **fft_size** (`int`) – The size of the Fourier transform to get the frequency response.
- **carrier_indexes** (`slice` | `np.ndarray` | `list[int]`) – The indexes of the subcarriers where signal is to be transmitted. If it is `None` assume all subcarriers will be used. This can be a slice object or a numpy array of integers.

Returns The received signal after transmission through the TDL channel

Return type `np.ndarray`

generate_impulse_response (`num_samples`: `int = 1`) → `None`

Generate a new impulse response of all discretized taps (not including possible zero padding) for `num_samples` channel realizations.

NOTE: This method is automatically called in the `corrupt_data` and `corrupt_data_in_freq_domain` methods and you don't need to call it before transmitting data. After one of them has been called the generated impulse response can be get with the `get_last_impulse_response` method.

The number of discretized taps of the generated impulse response will depend on the channel delay profile (the `tap_delays` passed during creation of the `TdlChannel` object) as well as on the sampling interval.

As an example, the COST259 TU channel profile has 20 different taps where the last one has a delay equal to 2.14 microseconds. If the sampling interval is configured as 3.25e-08 then the discretized channel will have more than 60 taps (including the zeros padding), where only 15 taps are different from zero. These 15 taps are what is returned by this method.

Alternatively, with a sampling time of 1e-6 you will end up with only 3 discretized taps.

Parameters `num_samples` (*int*) – The number of samples to generate (for each tap).

get_last_impulse_response() → *pyphysim.channels.fading.TdlImpulseResponse*

Get the last generated impulse response.

A new impulse response is generated when the method *corrupt_data* is called. You can use the *get_last_impulse_response* method to get the impulse response used to corrupt the last data.

Returns The impulse response of the channel that was used to corrupt the last data.

Return type *TdlImpulseResponse*

property num_rx_antennas

Get the number of receive antennas.

Returns The number of receive antennas.

Return type *int*

property num_taps

Number of taps not including zero taps after discretization.

Returns The number of taps (not including padding)

Return type *int*

property num_taps_with_padding

Number of taps including zero taps after discretization.

Returns The number of taps (including padding)

Return type *int*

property num_tx_antennas

Get the number of transmit antennas.

Returns The number of transmit antennas.

Return type *int*

set_num_antennas(*num_rx_antennas: int, num_tx_antennas: int*) → *None*

Set the number of transmit and receive antennas for MIMO transmission.

Set both *num_rx_antennas* and *num_tx_antennas* to *None* for SISO transmission

Parameters

- **num_rx_antennas** (*int*) – The number of receive antennas.
- **num_tx_antennas** (*int*) – The number of transmit antennas.

property switched_direction

Get the value of *switched_direction*.

Returns True if direction is switched and False otherwise.

Return type *bool*

```
class pyphysim.channels.fading.TdlChannelProfile (tap_powers_dB:          Op-
                                                    tional[numpy.ndarray]    =
                                                    None,      tap_delays:          Op-
                                                    tional[numpy.ndarray]    =  None,
                                                    name: str = 'custom')
```

Bases: *object*

Channel Profile class.

This class is just a nice way to present known profiles from the norm or the literature, which are represented as instances of this class.

A TDL channel profile store information about the TDL taps. That is, it stores the power and delay of each tap. The power and delay of each tap can be accessed through the `tap_powers_*` and `tap_delays` properties.

Some profiles are defined as objects of this class, such as `COST259_TUx`, `COST259_RAx` and `COST259_HTx`. These can be used when instantiating a `TdlChannel` object.

Note that the tap powers and delays are not necessarily *discretized* to some sampling interval.

Parameters

- **tap_powers_dB** (`np.ndarray`) – The tap powers (in dB). If both `tap_powers_dB` and `tap_delays` are None then a single tap with 0dB power will be assumed at delay 0.
- **tap_delays** (`np.ndarray`) – The tap delays.
- **name** (`str`) – A name for the channel profile

Examples

```
>>> jakes_generator = fading_generators.JakesSampleGenerator(Ts=3.25e-8)
>>> tdlchannel = TdlChannel(jakes_generator, channel_profile=COST259_TUx)
```

property Ts

Get the sampling interval used for discretizing this channel profile object.

If it is not discretized then this returns None.

Returns The sampling interval (in seconds).

Return type `float`, `None`

_calc_discretized_tap_powers_and_delays (`Ts: float`) → `Tuple[numpy.ndarray, numpy.ndarray]`

Discretize the taps according to the sampling time.

The discretized taps will be equally spaced and the delta time from two taps corresponds to the sampling time.

Parameters Ts (`float`) – The sampling time.

Returns A tuple with the discretized powers and delays.

Return type `np.ndarray`, `np.ndarray`

get_discretize_profile (`Ts: float`) → `pyphysim.channels.fading.TdlChannelProfile`

Compute the discretized taps (power and delay) and return a new discretized `TdlChannelProfile` object.

The tap powers and delays of the returned `TdlChannelProfile` object correspond to the taps and delays of the `TdlChannelProfile` object used to call `get_discretize_profile` after discretizing with the sampling interval `Ts`.

Parameters Ts (`float`) – The sampling time for the discretization of the tap powers and delays.

Returns The discretized channel profile

Return type `TdlChannelProfile`

property is_discretized

Returns True if the channel profile is discretized

property mean_excess_delay

The mean excess delay is the first moment of the power delay profile and is defined to be

$$\bar{\tau} = \frac{\sum_k P(\tau_k) \tau_k}{\sum_k P(\tau_k)}$$

Returns The mean excess delay.

Return type float

property name

Get the profile name.

Returns Profile name.

Return type str

property num_taps

Get the number of taps in the profile.

Returns Number of taps before discretization (does not count possible padding).

Return type int

property num_taps_with_padding

Get the number of taps in the profile including zero-padding when the profile is discretized.

If the profile is not discretized an exception is raised.

Returns Number of taps after discretization (it counts possible any added padding).

Return type int

property rms_delay_spread

The RMS delay spread is the square root of the second central moment of the power delay profile. It is defined to be

$$\sigma_t = \sqrt{\overline{t^2} - \bar{\tau}^2}$$

where

$$\overline{t^2} = \frac{\sum_k P(\tau_k) \tau_k^2}{\sum_k P(\tau_k)}$$

Typically, when the symbol time period is greater than 10 times the RMS delay spread, no ISI equalizer is needed in the receiver.

Returns The RMS delay spread.

Return type float

property tap_delays

Get the tap delays.

Returns The tap delays.

Return type np.ndarray

property tap_powers_dB

Get the tap powers (in dB).

Returns The tap powers (in dB).

Return type np.ndarray

property tap_powers_linear

Get the tap powers (in linear scale).

Returns The tap powers (in linear scale).

Return type `np.ndarray`

class `pyphysim.channels.fading.TdlImpulseResponse` (*tap_values*: `numpy.ndarray`,
channel_profile: `pyphysim.channels.fading.TdlChannelProfile`)

Bases: `object`

Class that represents impulse response for a `TdlChannel` object.

This impulse response corresponds to the generated samples for one or more channel realization of the `TdlChannel` with the configured fading generator.

Parameters

- **tap_values** (`np.ndarray`) – The tap_values (not including zero padded taps) of a TDL channel generated for the non-zero taps. Dimension: *Num sparse taps x SHAPE x num_samples*. The value SHAPE here is the shape of the fading generator and corresponds to independent impulse responses. Often the shape of the used fading generator is None and thus the dimension of *tap_values* is just *Num sparse taps x num_samples*
- **channel_profile** (`TdlChannelProfile`) – The channel profile that was considering to generate this impulse response.

property Ts

Return the sampling interval of this impulse response.

If the impulse response is not discretized this returns None.

Returns The sampling interval.

Return type `float`

_get_samples_including_the_extra_zeros () → `numpy.ndarray`

Return the *samples* including the zeros for the zero taps.

Returns `samples_with_zeros` – The samples including the extra delays containing zeros.

Return type `np.ndarray`

property channel_profile

Return the channel profile.

Returns The channel profile.

Return type `TdlChannelProfile`

static concatenate_samples (*impulse_responses*: `List[TdlImpulseResponse]`) → `pyphysim.channels.fading.TdlImpulseResponse`

Concatenate multiple `TdlImpulseResponse` objects and return the new concatenated `TdlImpulseResponse`.

This concatenation is performed in the “samples” dimension.

Parameters **impulse_responses** (`list[TdlImpulseResponse]`) – A list of `TdlImpulseResponse` objects to be concatenated.

Returns The new concatenated `TdlImpulseResponse`.

Return type `TdlImpulseResponse`

get_freq_response (*fft_size*: `int`) → `numpy.ndarray`

Get the frequency response for this impulse response.

Parameters `fft_size (int)` – The size of the FFT to be applied.

Returns The frequency response. Dimension: `fft_size x num_samples` for SISO impulse response or `fft_size x num_rx x num_tx x num_samples` for MIMO impulse response.

Return type `np.ndarray`

property `num_samples`

Get the number of samples (different, “neighbor” impulse responses) stored here.

Returns The number of samples in the *TdlImpulseResponse* object.

Return type `int`

plot_frequency_response (`fft_size: int`) → `None`

Plot the frequency response.

Parameters `fft_size (int)` – The size of the FFT to be applied.

plot_impulse_response () → `None`

Plot the impulse response.

property `tap_delays_sparse`

Return the tap delays (which are multiples of the sampling interval).

Returns The tap delays.

Return type `np.ndarray`

property `tap_indexes_sparse`

Return the (sparse) tap indexes.

Returns

Return type The indexes of the non-zero taps.

property `tap_values`

Return the tap values (including zero padding) as a numpy array.

Returns The tap values (including zero padding).

Return type `np.ndarray`

property `tap_values_sparse`

Return the tap values (not including zero padding) as a numpy array.

Returns The tap values (not including possible zero padding).

Return type `np.ndarray`

```
class pyphysim.channels.fading.TdlMimoChannel (fading_generator:
    Union[pyphysim.channels.fading_generators.JakesSampleGenerator,
    pyphysim.channels.fading_generators.RayleighSampleGenerator],
    channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile]
    = None, tap_powers_dB: Optional[numpy.ndarray] = None,
    tap_delays: Optional[numpy.ndarray] = None, Ts: Optional[float] = None)
```

Bases: `pyphysim.channels.fading.TdlChannel`

Tapped Delay Line channel model, which corresponds to a multipath channel.

You can create a new *TdlMimoChannel* object either specifying the channel profile or specifying both the channel tap powers and delays.

Note that the `TdlChannel` class can already work with multiple antennas if provided *fading_generator* has a shape with two elements (number of receive antennas and number of transmit antennas). The `TdlMimoChannel` only adds a slight better interface over `TdlChannel` class for working with MIMO. This class is also useful to test MIMO transmission, with the added *num_tx_antennas* and *num_rx_antennas* properties.

Parameters

- **fading_generator** (*FadingGenerator*) – The instance of a fading generator in the *fading_generators* module. It should be a subclass of `FadingSampleGenerator`. The fading generator will be used to generate the channel samples. The shape of the *fading_generator* will be ignored and replaced by provided number of antennas.
- **channel_profile** (*TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- **tap_powers_dB** (*np.ndarray*) – The powers of each tap (in dB). Dimension: $L \times 1$
Note: The power of each tap will be a negative number (in dB).
- **tap_delays** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: $L \times 1$

pyphysim.channels.fading_generators module

```
class pyphysim.channels.fading_generators.FadingSampleGenerator(shape: Optional[Union[int, Tuple[int, ...]]] = None)
```

Bases: `object`

Base class for fading generators.

Parameters *shape* (*tuple[int] | int, optional*) – The shape of the sample generator. Each time *generate_more_samples(num_samples)* method is called it will generate samples with this shape as the first dimensions.

generate_more_samples (*num_samples: Optional[int] = None*) → `None`

Generate next samples.

When implementing this method in a subclass you must take the value of the *self._shape* attribute into account.

Parameters *num_samples* (*int, optional*) – Number of samples (with the provided shape) to generate. If not provided it will be assumed to be 1.

get_samples () → `numpy.ndarray`

Get the last generated sample.

Returns

Return type `np.ndarray`

get_similar_fading_generator () → `Any`

Get a similar fading generator with the same configuration, but that generates independent samples.

property shape

Get the shape of the sampling generator

This is the shape of the samples that will be generated (not including *num_samples*).

Returns

Return type `tuple[int] | None`

skip_samples_for_next_generation (*num_samples: int*) → None

Advance sample generation process by *num_samples* similarly to what would happen if you call *generate_more_samples(num_samples=num_samples)*, but without actually generating the samples.

Parameters *num_samples* (*int*) – How many samples to skip.

```
class pyphysim.channels.fading_generators.JakesSampleGenerator (Fd: float = 100, Ts: float = 0.001, L: int = 8, shape: Optional[Union[int, Tuple[int, ... ]]] = None, RS: Optional[numpy.random.mtrand.RandomState] = None)
```

Bases: *pyphysim.channels.fading_generators.FadingSampleGenerator*

Class that generated fading samples according to the Jakes model given by

$$h(t) = \frac{1}{\sqrt{L}} \sum_{l=0}^{L-1} \exp\{j[2\pi f_D \cos(\phi_l)t + \psi_l]\}$$

Parameters

- **Fd** (*float*) – The Doppler frequency (in Hertz).
- **Ts** (*float*) – The sample interval (in seconds).
- **L** (*int*) – The number of rays for the Jakes model.
- **shape** (*int | tuple[int], optional*) – The shape of the sample generator. Each time the *generate_jakes_samples* method is called it will generate samples with this shape. If not provided, then 1 will be assumed. This could be used to generate MIMO channels. For instance, in order to generate channels samples for a MIMO scenario with 3 receive antennas and 2 transmit antennas use a shape of (3, 2).
- **RS** (*np.random.RandomState*) – The RandomState object used to generate the random values. If not provided, the global RandomState in numpy will be used.

See also:

generate_jakes_samples

property **Fd**

The Doppler frequency (in Hertz)

property **L**

The number of rays for the Jakes model

property **Ts**

The sample interval (in seconds)

_generate_time_samples (*num_samples: Optional[int] = None*) → *numpy.ndarray*

Generate the time samples that will be used internally in *generate_more_samples* method.

Parameters *num_samples* (*int, optional*) – Number of samples to be generated.

Returns The numpy array with the time samples. The shape of the generated time variable is “(1, A, num_samples)”, where ‘A’ has as many ‘1’s as the length of self._shape. Ex: If self._shape is None then the shape of the returned ‘t’ variable is (1, num_samples). If self._shape is (2,3) then the shape of the returned ‘t’ variable is (1, 1, 1, num_samples)

Return type *np.ndarray*

Notes

Each time `_generate_time_samples` is called it will update `_current_time` to reflect the advance of the time after generating the new samples.

`_set_phi_and_psi_according_to_shape()` → `None`

This will update the phi and psi attributes used to generate the jakes samples to reflect the current value of `self._shape`.

`generate_more_samples(num_samples: Optional[int] = None)` → `None`

Generate next samples.

Note that any subsequent call to this method continues from the point where the last call stopped. That is, if you generate 10 samples and then 15 more samples, you will get the same samples you would have got if you had generated 25 samples.

Parameters `num_samples` (`int`, *optional*) – Number of samples (with the provided shape) to generate. If not provided it will be assumed to be 1.

Notes

This method will update the `self._current_time` variable.

`get_similar_fading_generator()` → `Any`

Get a similar fading generator with the same configuration, but that generates independent samples.

Returns Another `JakesSampleGenerator` object with the same configuration of this object.

Return type `JakesSampleGenerator`

property `shape`

Get the shape of the sampling generator

This is the shape of the samples that will be generated (not including `num_samples`).

Returns

Return type `tuple[int] | None`

`skip_samples_for_next_generation(num_samples: int)` → `None`

Advance sample generation process by `num_samples` similarly to what would happen if you call `generate_more_samples(num_samples=num_samples)`, but without actually generating the samples.

This has the effect of advancing the internal time using by `JakesSampleGenerator` without generating any samples.

Parameters `num_samples` (`int`) – How many samples to skip.

```
class pyphysim.channels.fading_generators.RayleighSampleGenerator(shape: Op-
                                                                    tional[Union[int,
                                                                    Tuple[int,
                                                                    ... ]]] =
                                                                    None)
```

Bases: `pyphysim.channels.fading_generators.FadingSampleGenerator`

Class that generates fading samples from a Raleigh distribution.

Parameters `shape` (`int` | `tuple[int]` | `None`) – The shape of the sample generator. Each time the `generate_jakes_samples` method is called it will generate samples with this shape. If not provided, then 1 will be assumed.

generate_more_samples (*num_samples: Optional[int] = None*) → *None*

Generate next samples.

Parameters *num_samples* (*int*, *optional*) – Number of samples (with the provided shape) to generate. If not provided it will be assumed to be 1.

get_similar_fading_generator () → *Any*

Get a similar fading generator with the same configuration, but that generates independent samples.

Returns Another RayleighSampleGenerator object with the same configuration of this object.

Return type *RayleighSampleGenerator*

skip_samples_for_next_generation (*num_samples: int*) → *None*

Advance sample generation process by *num_samples* similarly to what would happen if you call *generate_more_samples(num_samples=num_samples)*, but without actually generating the samples.

Since the samples generated by RayleighSampleGenerator are independent, calling this method has no effect.

Parameters *num_samples* (*int*) – How many samples to skip. This is ignored in the RayleighSampleGenerator. Since the different samples are uncorrelated then calling *skip_samples_for_next_generation* does not do anything.

`pyphysim.channels.fading_generators.generate_jakes_samples` (*Fd: float, Ts: float*
= 0.001, *NSamples:*
int = 100, *L: int*
= 8, *shape: Op-*
tional[Tuple[int, ...]]
= *None*, *current_time:*
float = 0, *phi_l: Op-*
tional[numpy.ndarray]
= *None*, *psi_l: Op-*
tional[numpy.ndarray]
= *None*) →
Tuple[float,
numpy.ndarray]

Generates channel samples according to the Jakes model.

This functions generates channel samples for a single tap according to the Jakes model given by

$$h(t) = \frac{1}{\sqrt{L}} \sum_{l=0}^{L-1} \exp\{j[2\pi f_D \cos(\phi_l)t + \psi_l]\} \quad (1.1)$$

Parameters

- **Fd** (*float*) – The Doppler frequency (in Hertz).
- **Ts** (*float*) – The sample interval (in seconds).
- **NSamples** (*int*) – The number of samples to generate.
- **L** (*int*) – The number of rays for the Jakes model.
- **shape** (*tuple[int]*) – The shape of the generated channel. This is used to generate MIMO channels. For instance, in order to generate channels samples for a MIMO scenario with 3 receive antennas and 2 transmit antennas use a shape of (3, 2).
- **current_time** (*float*) – The current start time
- **phi_l** (*np.ndarray*) – The “phi” part in Jakes model
- **psi_l** (*np.ndarray*) – The “psi” part in Jakes model

Returns

The **first element** in the returned tuple is the **new current time** (that should be used the next time this function is called to 'continue' the fading).

The **second element** in the returned tuple is the **generated channel**. If *shape* is None the the shape of the returned *h* is equal to (NSamples,). That is, *h* is a 1-dimensional numpy array. If *shape* was provided then the shape of *h* is the provided shape with an additional dimension for the time (the last dimension). For instance, if a *shape* of (3, 2) was provided then the shape of the returned *h* will be (3, 2, NSamples).

Return type (float, np.ndarray)

pyphysim.channels.multuser module

Module containing multuser channels.

The *MultiUserChannelMatrix* and *MultiUserChannelMatrixExtInt* classes implement the MIMO Interference Channel (MIMO-IC) model, where the first one does not include an external interference source while the last one includes it. The MIMO-IC model is shown in the Figure below.

Fig. 1: MIMO Interference Channel

```
class pyphysim.channels.multuser.MuChannel (N: Union[int, Tuple[int,
int]], fading_generator: Optional[Union[pyphysim.channels.fading_generators.JakesSampleGen
pyphysim.channels.fading_generators.RayleighSampleGenerator]]
= None, channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile]
= None, tap_powers_dB: Optional[numpy.ndarray] = None, tap_delays:
Optional[numpy.ndarray] = None, Ts: Optional[float] = None)
```

Bases: `object`

SISO multuser channel.

Each transmitter sends data to its own receiver while interfering to other receivers.

Note that noise is NOT added.

Parameters

- **N** (*int* | *tuple[int, int]*) – The number of transmit/receive pairs.
- **fading_generator** (*T* ≤ *fading_generators.FadingSampleGenerator*) – The instance of a fading generator in the *fading_generators* module. It should be a subclass of *FadingSampleGenerator*. The fading generator will be used to generate the channel samples. However, since we have multiple links, the provided fading generator will actually be used to create similar (but independent) fading generators. If not provided then *RayleighSampleGenerator* will be used
- **channel_profile** (*TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- **tap_powers_dB** (*np.ndarray*) – The powers of each tap (in dB). Dimension: *L* × *I*
Note: The power of each tap will be a negative number (in dB).
- **tap_delays** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: *L* × *I*

Returns The created object.

Return type *MuChannel*

property channel_profile

Return the channel profile.

Returns The channel profile.

Return type *TdlChannelProfile*

corrupt_data (*signal*: *numpy.ndarray*) → *numpy.ndarray*

Corrupt data passed through the TDL channels of each link.

Note that noise is NOT added in *corrupt_data*.

Parameters **signal** (*np.ndarray*) – Signal to be transmitted through the channel. This should be a 2D numpy array (1D array if there is only one transmitter), where each row corresponds to the transmit data of one transmitter.

Returns Received signal at each receiver. Each row corresponds to one receiver.

Return type *np.ndarray*

corrupt_data_in_freq_domain (*signal*: *numpy.ndarray*, *fft_size*: *int*, *carrier_indexes*: *Union[numpy.ndarray, List[int], slice] = None*) → *numpy.ndarray*

Corrupt data passed through the TDL channels of each link, but in the frequency domain..

For each link, this is ROUGHLY equivalent to modulating *signal* with OFDM using *fft_size* subcarriers, transmitting through a regular *TdlChannel*, and then demodulating with OFDM to recover the received signal.

One important difference is that here the channel is considered constant during the transmission of *fft_size* elements in *signal*, and then it is varied by the equivalent of the variation for that number of elements. That is, the channel is block static.

Note that noise is NOT added in *corrupt_data*.

Parameters

- **signal** (*np.ndarray* | *list[np.ndarray]*) – Signal to be transmitted through the channel. This should be a 2D numpy array where each row corresponds to the transmit data of one transmitter. It can also be a list of numpy arrays or, if there is only one transmitter, a single 1D numpy array.
- **fft_size** (*int*) – The size of the Fourier transform to get the frequency response.
- **carrier_indexes** (*slice* | *np.ndarray* | *list[int]*) – The indexes of the subcarriers where signal is to be transmitted (all users will use the same indexes). If it is None assume all subcarriers will be used.

Returns Received signal at each receiver. Each row corresponds to one receiver.

Return type *np.ndarray*

get_last_impulse_response (*rx_idx*: *int*, *tx_idx*: *int*) → *py-physim.channels.fading.TdlImpulseResponse*

Get the last generated impulse response.

A new impulse response is generated when the method *corrupt_data* is called. You can use the *get_last_impulse_response* method to get the impulse response used to corrupt the last data.

Parameters

- **rx_idx** (*int*) – The index of the receiver.

- **tx_idx** (*int*) – The index of the transmitter

Returns The impulse response of the channel that was used to corrupt the last data for the link from transmitter *tx_idx* to receiver *rx_idx*.

Return type *TdlImpulseResponse*

property num_rx_antennas

Get the number of receive antennas.

Returns The number of receive antennas.

Return type *int*

property num_taps

Get the number of taps in the profile.

Note that all links have the same channel profile.

Returns The number of taps in the channel (not including any zero padding).

Return type *int*

property num_taps_with_padding

Get the number of taps in the profile including zero-padding when the profile is discretized.

If the profile is not discretized an exception is raised.

Note that all links have the same channel profile.

Returns The number of taps in the channel (including any zero padding).

Return type *int*

property num_tx_antennas

Get the number of transmit antennas.

Returns The number of transmit antennas.

Return type *np.ndarray*

property pathloss_matrix

Get the matrix with the pathloss from each transmitter to each receiver.

Returns The pathloss matrix, if it was set, or None if there is no pathloss.

Return type *np.ndarray*

set_pathloss (*pathloss_matrix*: *numpy.ndarray*) → *None*

Set the path loss (IN LINEAR SCALE) from each transmitter to each receiver.

The path loss will be accounted when calling the *corrupt_data* method.

If you want to disable the path loss, set *pathloss_matrix* to None.

Parameters **pathloss_matrix** (*np.ndarray*) – A matrix with dimension “K x K”, where K is the number of users, with the path loss (IN LINEAR SCALE) from each transmitter (columns) to each receiver (rows). If you want to disable the path loss then set it to None.

Notes

Note that path loss is a power relation, which means that the channel coefficients will be multiplied by the square root of elements in *pathloss_matrix*.

property `switched_direction`

Get the value of *switched_direction*.

Returns True if direction is switched and False otherwise.

Return type `bool`

```
class pyphysim.channels.multiuser.MuMimoChannel (N: Union[int, Tuple[int, int]],
                                                num_rx_antennas: int,
                                                num_tx_antennas: int,
                                                fading_generator: Optional[Union[pyphysim.channels.fading_generators.JakesSampleGenerator,
pyphysim.channels.fading_generators.RayleighSampleGenerator]] = None,
                                                channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile] = None,
                                                tap_powers_dB: Optional[numpy.ndarray] = None,
                                                tap_delays: Optional[numpy.ndarray] = None,
                                                Ts: Optional[float] = None)
```

Bases: `pyphysim.channels.multiuser.MuChannel`

MIMO multiuser channel.

Each transmitter sends data to its own receiver while interfering to other receivers.

Note that noise is NOT added.

Parameters

- ***N*** (*int* | *tuple*[*int*, *int*]) – The number of transmit/receive pairs.
- ***num_rx_antennas*** (*int*) – Number of receive antennas of each user.
- ***num_tx_antennas*** (*int*) – Number of transmit antennas of each user.
- ***fading_generator*** (*T* <= *fading_generators.FadingSampleGenerator*) – The instance of a fading generator in the *fading_generators* module. It should be a subclass of *FadingSampleGenerator*. The fading generator will be used to generate the channel samples. However, since we have multiple links, the provided fading generator will actually be used to create similar (but independent) fading generators. If not provided then *RayleighSampleGenerator* will be used
- ***channel_profile*** (*TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- ***tap_powers_dB*** (*np.ndarray*) – The powers of each tap (in dB). Dimension: *L* x *I*
Note: The power of each tap will be a negative number (in dB).
- ***tap_delays*** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: *L* x *I*

```
class pyphysim.channels.multiuser.MultiUserChannelMatrix
```

Bases: `object`

Stores the (fast fading) channel matrix of a multi-user scenario. The path-loss from each transmitter to each receiver is also be accounted if the *set_pathloss* is called to set the path-loss matrix.

This channel matrix can be seen as an concatenation of blocks (of non-uniform size) where each block is a channel from one transmitter to one receiver and the block size is equal to the number of receive antennas of the receiver times the number of transmit antennas of the transmitter.

For instance, in a 3-users scenario the block (1,0) corresponds to the channel between the transmit antennas of user 0 and the receive antennas of user 1 (indexing starting at zero). If the number of receive antennas and transmit antennas of the three users are [2, 4, 6] and [2, 3, 5], respectively, then the block (1,0) would have a dimension of 4x2. Likewise, the channel matrix would look similar to the block structure below.

| | | |
|-------|-------|-------|
| 2 x 2 | 2 x 3 | 2 x 5 |
| 4 x 2 | 4 x 3 | 4 x 5 |
| 6 x 2 | 6 x 3 | 6 x 5 |

It is possible to initialize the channel matrix randomly by calling the *randomize* method, or from a given matrix by calling the *init_from_channel_matrix* method.

In order to get the channel matrix of a specific user *k* to another user *l*, call the *get_Hkl* method.

property H

Get method for the H property.

Returns The channel from all transmitters to all receivers. This is a numpy array of numpy arrays.

Return type np.ndarray

property K

Get method for the K property.

Returns The number of users (transmit-receive pairs).

Return type int

property Nr

Get method for the Nr property.

Returns The number of receive antennas of all users.

Return type np.ndarray

property Nt

Get method for the Nt property.

Returns The number of transmit antennas of all users.

Return type np.ndarray

property W

Post processing filters (a list of 2D numpy arrays) for each user.

Returns The Post processing filters for each user.

Return type list[np.ndarray]

_calc_Bkl_cov_matrix_all_l (*F_all_users*: *numpy.ndarray*, *k*: *int*, *N0_or_Rek*: *NumberOrArray = 0.0*) → *numpy.ndarray*

Calculates the interference-plus-noise covariance matrix for all streams at receiver *k* according to equation (28) in [Cadambe2008].

The interference-plus-noise covariance matrix for stream *l* of user *k* is given by Equation (28) in [Cadambe2008], which is reproduced below

$$[k]l = \sum_{j=1}^K \frac{P^{[j]}}{d^{[j]}} \sum_{d=1}^{d^{[j]}} \frac{[kj][j][j]^\dagger[kj]^\dagger}{\star l \star l} - \frac{P^{[k]}}{d^{[k]}} \frac{[kk][k][k]^\dagger[kk]^\dagger}{\star l \star l} + N^{[k]}$$

where $P^{[k]}$ is the transmit power of transmitter k , $d^{[k]}$ is the number of degrees of freedom of user k , $[k,j]$ is the channel between transmitter j and receiver k , \star_l is the l -th column of the precoder of user k and I_{N_k} is an identity matrix with size equal to the number of receive antennas of receiver k .

Parameters

- **F_all_users** (*list*[*np.ndarray*] | *np.ndarray*) – The precoder of all users (already taking into account the transmit power). This can be a list of numpy arrays or a 1D numpy array of numpy arrays.
- **k** (*int*) – Index of the desired user.
- **N0_or_Rek** (*float* | *np.ndarray*) – If this is a 2D numpy array, it is interpreted as the covariance matrix of any external interference plus noise. If this is a number, it is interpreted as the noise power, in which case the covariance matrix will be an identity matrix times this noise power.

Returns Bkl – Covariance matrix of all streams of user k . Each element of the returned 1D numpy array is a 2D numpy complex array corresponding to the covariance matrix of one stream of user k .

Return type *np.ndarray*

Notes

To be simple, a function that returns the covariance matrix of only a single stream “ l ” of the desired user “ k ” could be implemented, but in the order to calculate the max SINR algorithm we need the covariance matrix of all streams and returning them in single function as is done here allows us to calculate the first part in equation (28) of [Cadambe2008] only once, since it is the same for all streams.

_calc_Bkl_cov_matrix_first_part (*F_all_users*: *numpy.ndarray*, *k*: *int*, *N0_or_Rek*: *Num-berOrArray = 0.0*) → *numpy.ndarray*

Calculates the first part in the equation of the Bkl covariance matrix in equation (28) of [Cadambe2008].

The first part is given by

$$\sum_{j=1}^K \frac{P^{[j]}}{d^{[j]}} \sum_{d=1}^{d^{[j]}} \frac{[kj][j]}{\star d} \frac{[j]^\dagger [kj]^\dagger}{\star d} + N_k$$

Note that it only depends on the value of k .

Parameters

- **F_all_users** (*list*[*np.ndarray*] | *np.ndarray*) – The precoder of all users (already taking into account the transmit power). It can be a list of numpy arrays or a numpy array of numpy arrays.
- **k** (*int*) – Index of the desired user.
- **N0_or_Rek** (*float* | *np.ndarray*) – If this is a 2D numpy array, it is interpreted as the covariance matrix of any external interference plus noise. If this is a number, it is interpreted as the noise power, in which case the covariance matrix will be an identity matrix times this noise power.

Returns first_part

Return type *np.ndarray*

_calc_Bkl_cov_matrix_second_part (*Fk*: *numpy.ndarray*, *k*: *int*, *l*: *int*) → *numpy.ndarray*

Calculates the second part in the equation of the Bkl covariance matrix in equation (28) of [Cadambe2008] (note that it does not include the identity matrix).

The second part is given by

$$\frac{P^{[k]} [kk] [k] [k]^\dagger [kk]^\dagger}{d^{[k]} \star l \star l}$$

Parameters

- **Fk** (*np.ndarray*) – The precoder of the desired user.
- **k** (*int*) – Index of the desired user.
- **l** (*int*) – Index of the desired stream.

Returns **second_part** – Second part in equation (28) of [Cadambe2008].

Return type *np.ndarray*

_calc_JP_Bkl_cov_matrix_all_l (*F_all_users: numpy.ndarray, k: int, NO_or_Rek: Num-berOrArray = 0.0*) → *numpy.ndarray*

Calculates the interference-plus-noise covariance matrix for all streams at receiver k according to equation (28) in [Cadambe2008].

The interference-plus-noise covariance matrix for stream l of user k is given by Equation (28) in [Cadambe2008], which is reproduced below

$$[kl] = \sum_{j=1}^K \frac{P^{[j]}}{d^{[j]} \star l \star l} \sum_{d=1}^{d^{[j]}} [kj] [j] [j]^\dagger [kj]^\dagger - \frac{P^{[k]} [kk] [k] [k]^\dagger [kk]^\dagger}{d^{[k]} \star l \star l} + N^{[k]}$$

where $P^{[k]}$ is the transmit power of transmitter k , $d^{[k]}$ is the number of degrees of freedom of user k , $[kj]$ is the channel between transmitter j and receiver k , $\star l$ is the l -th column of the precoder of user k and $N^{[k]}$ is an identity matrix with size equal to the number of receive antennas of receiver k .

Parameters

- **F_all_users** (*list[np.ndarray] | np.ndarray*) – The precoder of all users (already taking into account the transmit power). This can be either a 1D numpy array of numpy arrays or a list of numpy arrays.
- **k** (*int*) – Index of the desired user.
- **NO_or_Rek** (*float | np.ndarray*) – If this is a 2D numpy array, it is interpreted as the covariance matrix of any external interference plus noise. If this is a number, it is interpreted as the noise power, in which case the covariance matrix will be an identity matrix times this noise power.

Returns **Bkl** – Covariance matrix of all streams of user k . Each element of the returned 1D numpy array is a 2D numpy complex array corresponding to the covariance matrix of one stream of user k .

Return type *np.ndarray*

Notes

To be simple, a function that returns the covariance matrix of only a single stream “ l ” of the desired user “ k ” could be implemented, but in the order to calculate the max SINR algorithm we need the covariance matrix of all streams and returning them in single function as is done here allows us to calculate the first part in equation (28) of [Cadambe2008] only once, since it is the same for all streams.

_calc_JP_Bkl_cov_matrix_first_part (*F_all_users: numpy.ndarray, k: int, noise_power: float = 0.0*) → *numpy.ndarray*

Calculates the first part in the equation of the Bkl covariance matrix in equation (28) of [Cadambe2008] when joint process is employed.

The first part is given by

$$\sum_{j=1}^K \frac{P^{[j]}}{d^{[j]}} \sum_{d=1}^{d^{[j]}} \frac{[kj][j][j]^\dagger [kj]^\dagger}{\star d \star d} + Nk$$

Note that it only depends on the value of k .

Parameters

- **F_all_users** (*list* [*np.ndarray*] | *np.ndarray*) – The precoder of all users (already taking into account the transmit power). It can be a list of numpy arrays or a numpy array of numpy arrays.
- **k** (*int*) – Index of the desired user.
- **noise_power** (*float* | *None*, *optional*) – The noise power.

Returns

Return type *np.ndarray*

_calc_JP_Bkl_cov_matrix_first_part_impl (*Hk*: *numpy.ndarray*, *F_all_users*: *numpy.ndarray*, *Rek*: *NumberOrArray*)
→ *numpy.ndarray*

Common implementation of the `_calc_JP_Bkl_cov_matrix_first_part`.

Parameters

- **Hk** (*np.ndarray*) – The channel from all transmitters (not including external interference source, if any) to receiver k .
- **F_all_users** (*list* [*np.ndarray*]) – The precoder of all users (already taking into account the transmit power).
- **Rek** (*np.ndarray* | *float*) – Covariance matrix of the external interference (if there is any) plus noise.

Returns The *first_part* for the Bkl matrix computation.

Return type *np.ndarray*

_calc_JP_Bkl_cov_matrix_second_part (*Fk*: *numpy.ndarray*, *k*: *int*, *l*: *int*) → *numpy.ndarray*

Calculates the second part in the equation of the Blk covariance matrix in equation (28) of [Cadambe2008] (note that it does not include the identity matrix).

The second part is given by

$$\frac{P^{[k]}}{d^{[k]}} \frac{[kk][k][k]^\dagger [kk]^\dagger}{\star l \star l}$$

Parameters

- **Fk** (*np.ndarray*) – The precoder of the desired user.
- **k** (*int*) – Index of the desired user.
- **l** (*int*) – Index of the desired stream.

Returns *second_part* – Second part in equation (28) of [Cadambe2008].

Return type *np.ndarray*.

static _calc_JP_Bkl_cov_matrix_second_part_impl (*Hk*: *numpy.ndarray*, *Fk*: *numpy.ndarray*, *l*: *int*) → *numpy.ndarray*

Common implementation of the `_calc_JP_Bkl_cov_matrix_second_part` method.

Parameters

- **Hk** (*np.ndarray*) –
- **Fk** (*np.ndarray*) –
- **l** (*int*) –

Returns**Return type** *np.ndarray***_calc_JP_Q_impl** (*k: int, F_all_users: numpy.ndarray*) → *numpy.ndarray*

Calculates the interference covariance matrix (without any noise) at the *k*-th receiver with a joint processing scheme.

See the documentation of the `calc_JP_Q` method.

Parameters

- **k** (*int*) – The user index.
- **F_all_users** (*list[np.ndarray] | np.ndarray*) – The precoders of all users. It can be a list of numpy arrays or a numpy array of numpy arrays.

Returns The interference covariance matrix (without any noise).**Return type** *np.ndarray***_calc_JP_SINR_k** (*k: int, Fk: numpy.ndarray, Uk: numpy.ndarray, Bkl_all_l: numpy.ndarray*) → *numpy.ndarray*

Calculates the SINR of all streams of user ‘k’.

Parameters

- **k** (*int*) – Index of the desired user.
- **Fk** (*np.ndarray*) – The precoder of user k.
- **Uk** (*np.ndarray*) – The receive filter of user k (before applying the conjugate transpose).
- **Bkl_all_l** (*list[np.ndarray] | np.ndarray*) – A sequence (1D numpy array, a list, etc) of 2D numpy arrays corresponding to the Bkl matrices for all ‘l’s.

Returns **SINR_k** – The SINR for the different streams of user k.**Return type** *np.ndarray***static _calc_JP_SINR_k_impl** (*Hk: numpy.ndarray, Fk: numpy.ndarray, Uk: numpy.ndarray, Bkl_all_l: numpy.ndarray*) → *numpy.ndarray*

Implementation of the `_calc_JP_SINR_k()` method.

Parameters

- **Hk** (*np.ndarray*) – Channel from all transmitters to receiver k.
- **Fk** (*np.ndarray*) – The precoder of user k.
- **Uk** (*np.ndarray*) – The receive filter of user k (before applying the conjugate transpose).
- **Bkl_all_l** (*list[np.ndarray]*) – A sequence (1D numpy array, a list, etc) of 2D numpy arrays corresponding to the Bkl matrices for all ‘l’s.

Returns **SINR_k** – The SINR for the different streams of user k.**Return type** *np.ndarray*

Notes

The implementation of the `_calc_JP_SINR_k` method is almost the same for the `MultiuserChannelMatrix` and `MultiuserChannelMatrixExtint` class, except for the Hk argument. Therefore, the common code was put here and in each class the `_calc_JP_SINR_k()` is implemented as simply getting the correct Hk argument and then calling `_calc_JP_SINR_k_impl()`.

`_calc_Q_impl(k: int, F_all_users: numpy.ndarray) → numpy.ndarray`

Calculates the interference covariance matrix (without any noise) at the k -th receiver.

See the documentation of the `calc_Q` method.

Parameters

- **k** (*int*) – Index of the desired receiver.
- **F_all_users** (*np.ndarray*) – The precoder of all users (already taking into account the transmit power). This should be a 1D numpy array of 2D numpy arrays.

Returns

Return type `np.ndarray`

`_calc_SINR_k(k: int, Fk: numpy.ndarray, Uk: numpy.ndarray, Bkl_all_l: numpy.ndarray) → numpy.ndarray`

Calculates the SINR of all streams of user 'k'.

Parameters

- **k** (*int*) – Index of the desired user.
- **Fk** (*np.ndarray*) – The precoder of user k.
- **Uk** (*np.ndarray*) – The receive filter of user k (before applying the conjugate transpose).
- **Bkl_all_l** (*list[np.ndarray] | np.ndarray*) – A sequence (1D numpy array, a list, etc) of 2D numpy arrays corresponding to the B_{kl} matrices for all 'l's.

Returns `SINR_k` – The SINR for the different streams of user k.

Return type `np.ndarray`

`static _from_small_matrix_to_big_matrix(small_matrix: numpy.ndarray, Nr: numpy.ndarray, Nt: numpy.ndarray, Kr: int, Kt: Optional[int] = None) → numpy.ndarray`

Convert from a small matrix to a big matrix by repeating elements according to the number of receive and transmit antennas.

Parameters

- **small_matrix** (*np.ndarray*) – Any 2D numpy array
- **Nr** (*np.ndarray*) – Number of antennas at each receiver. This should be a 1D numpy array.
- **Nt** (*np.ndarray*) – Number of antennas at each transmitter. This should be a 1D numpy array.
- **Kr** (*int*) – Number of receivers to consider.
- **Kt** (*int, optional*) – Number of transmitters to consider. If not provided the value of `Kr` will be used.

Returns `big_matrix` – The converted matrix. This is a 2D numpy array

Return type np.ndarray

Notes

Since a ‘user’ is a transmit/receive pair then the `small_matrix` will be a square matrix and Kr must be equal to Kt . However, in the `MultiUserChannelMatrixExtInt` class we will only have the ‘transmitter part’ for the external interference sources. That means that `small_matrix` will have more columns than rows and Kt will be greater than Kr .

Examples

```
>>> K = 3
>>> Nr = np.array([2, 4, 6])
>>> Nt = np.array([2, 3, 5])
>>> small_matrix = np.array([[1,2,3],[4,5,6],[7,8,9]])
>>> MultiUserChannelMatrix._from_small_matrix_to_big_matrix(
    ↪small_matrix, Nr, Nt, K)
array([[1, 1, 2, 2, 2, 3, 3, 3, 3, 3],
       [1, 1, 2, 2, 2, 3, 3, 3, 3, 3],
       [4, 4, 5, 5, 5, 6, 6, 6, 6, 6],
       [4, 4, 5, 5, 5, 6, 6, 6, 6, 6],
       [4, 4, 5, 5, 5, 6, 6, 6, 6, 6],
       [4, 4, 5, 5, 5, 6, 6, 6, 6, 6],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9],
       [7, 7, 8, 8, 8, 9, 9, 9, 9, 9]])
```

property big_H

Get method for the `big_H` property.

Returns The channel from all transmitters to all receivers as a single big matrix (numpy complex array)

Return type np.ndarray

property big_W

Post processing filters (a block diagonal matrix) for each user.

Returns The big block diagonal matrix with the post processing filters for each user.

Return type np.ndarray

calc_JP_Q (k : `int`, F_all_users : `numpy.ndarray`) → `numpy.ndarray`

Calculates the interference plus noise covariance matrix at the k -th receiver with a joint processing scheme.

The interference covariance matrix at the k -th receiver, k , is given by

$$k = \sum_{j=1, j \neq k}^K \frac{P_j}{Ns_j} j_{j \ k}^{HH}$$

where P_j is the transmit power of transmitter j , and Ns_j is the number of streams for user j .

Parameters

- **k** (`int`) – Index of the desired receiver.
- **F_all_users** (`np.ndarray` | `list[np.ndarray]`) – The precoder of all users (already taking into account the transmit power).

Returns \mathbf{Q}_k – The interference covariance matrix at receiver k .

Return type np.ndarray

calc_JP_SINR (F : *numpy.ndarray*, U : *numpy.ndarray*) → *numpy.ndarray*

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the noise_var property.

Parameters

- \mathbf{F} (*np.ndarray*) – The precoders of all users. This should be a 1D numpy array of 2D numpy arrays.
- \mathbf{U} (*np.ndarray*) – The receive filters of all users. This should be a 1D numpy array of 2D numpy arrays.

Returns SINRs – The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats).

Return type np.ndarray

calc_Q (k : *int*, $F_{\text{all_users}}$: *numpy.ndarray*) → *numpy.ndarray*

Calculates the interference plus noise covariance matrix at the k -th receiver.

The interference covariance matrix at the k -th receiver, k , is given by

$$\mathbf{Q}_k = \sum_{j=1, j \neq k}^K \frac{P_j}{N s_j} \mathbf{h}_{kj}^H \mathbf{h}_{kj}$$

where P_j is the transmit power of transmitter j , and $N s_j$ is the number of streams for user j .

Parameters

- k (*int*) – Index of the desired receiver.
- $\mathbf{F}_{\text{all_users}}$ (*np.ndarray*) – The precoder of all users (already taking into account the transmit power). This should be a 1D numpy array of 2D numpy arrays.

Returns \mathbf{Q}_k – The interference covariance matrix at receiver k (a 2D numpy complex array).

Return type np.ndarray

calc_SINR (F : *numpy.ndarray*, U : *numpy.ndarray*) → *numpy.ndarray*

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the noise_var property.

Parameters

- \mathbf{F} (*np.ndarray*) – The precoders of all users. This should be a 1D numpy array of 2D numpy arrays.
- \mathbf{U} (*np.ndarray*) – The receive filters of all users. This should be a 1D numpy array of 2D numpy arrays.

Returns SINRs – The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats)

Return type np.ndarray

corrupt_concatenated_data ($data$: *numpy.ndarray*) → *numpy.ndarray*

Corrupt data passed through the channel.

If self.noise_var is set to some scalar number then white noise will also be added.

Parameters **data** (*np.ndarray*) – A bi-dimensional numpy array with the concatenated data of all transmitters. The dimension of data is $\text{sum}(\text{self.Nt}) \times \text{NSymb}$. That is, the number of rows corresponds to the sum of the number of transmit antennas of all users and the number of columns correspond to the number of transmitted symbols.

Returns A bi-dimension numpy array where the number of rows corresponds to the sum of the number of receive antennas of all users and the number of columns correspond to the number of transmitted symbols.

Return type *np.ndarray*

corrupt_data (*data: numpy.ndarray*) → *numpy.ndarray*

Corrupt data passed through the channel.

If the noise_var is supplied then an white noise will also be added.

Parameters **data** (*np.ndarray*) – An array of numpy matrices with the data of the multiple users. The k -th element in *data* is a numpy array with dimension $\text{Nt}_k \times \text{NSymb}$, where Nt_k is the number of transmit antennas of the k -th user and NSymb is the number of transmitted symbols.

Returns A numpy array where each element contains the received data (a 2D numpy array) of a user.

Return type *np.ndarray*

get_Hk (*k: int*) → *numpy.ndarray*

Get the channel from all transmitters to receiver k .

Parameters **k** (*int*) – Receiving user.

Returns **channel_k** – Channel from all transmitters to receiver k . This is a 2D numpy array.

Return type *np.ndarray*

See also:

get_Hkl()

Examples

```
>>> multiH = MultiUserChannelMatrix()
>>> H = np.reshape(np.r_[0:16], [4,4])
>>> Nt = np.array([2, 2])
>>> Nr = np.array([2, 2])
>>> multiH.init_from_channel_matrix(H, Nr, Nt, 2)
>>> print(multiH.big_H)
[[ 0  1  2  3]
 [ 4  5  6  7]
 [ 8  9 10 11]
 [12 13 14 15]]
>>> print(multiH.get_Hk(0))
[[0 1 2 3]
 [4 5 6 7]]
>>> print(multiH.get_Hk(1))
[[ 8  9 10 11]
 [12 13 14 15]]
```

get_Hkl (*k: int, l: int*) → *numpy.ndarray*

Get the channel matrix from user l to user k .

Parameters

- **l** (*int*) – Transmitting user.
- **k** (*int*) – Receiving user.

Returns **channel** – Channel from transmitter *l* to receiver *k*. This is a 2D numpy array.

Return type np.ndarray

See also:

`get_Hk()`

Examples

```
>>> multiH = MultiUserChannelMatrix()
>>> H = np.reshape(np.r_[0:16], [4,4])
>>> Nt = np.array([2, 2])
>>> Nr = np.array([2, 2])
>>> multiH.init_from_channel_matrix(H, Nr, Nt, 2)
>>> print(multiH.big_H)
[[ 0  1  2  3]
 [ 4  5  6  7]
 [ 8  9 10 11]
 [12 13 14 15]]
>>> print(multiH.get_Hkl(0, 0))
[[0 1]
 [4 5]]
>>> print(multiH.get_Hkl(1, 0))
[[ 8  9]
 [12 13]]
```

init_from_channel_matrix(*channel_matrix*: *numpy.ndarray*, *Nr*: *Union[numpy.ndarray, int]*,
Nt: *Union[numpy.ndarray, int]*, *K*: *int*) → *None*
Initializes the multiuser channel matrix from the given *channel_matrix*.

Parameters

- **channel_matrix** (*np.ndarray*) – A matrix concatenating the channel of all users (from each transmitter to each receiver). This is a 2D numpy array.
- **Nr** (*int* | *np.ndarray*) – Number of antennas at each receiver.
- **Nt** (*int* | *np.ndarray*) – Number of antennas at each transmitter.
- **K** (*int*) – Number of transmit/receive pairs.

Raises **ValueError** – If the arguments are invalid.

property last_noise

Get method for the last_noise property.

Returns The last AWGN noise array added to corrupt the data.

Return type None | np.ndarray

property noise_var

Get method for the noise_var property.

Returns The noise variance, if noise is being added in “corrupt_*data” methods.

Return type None | float

property pathloss

Get method for the pathloss property.

Returns The pathloss matrix (if one was set).

Return type None | np.ndarray

randomize (*Nr*: Union[*numpy.ndarray*, *int*], *Nt*: Union[*numpy.ndarray*, *int*], *K*: *int*) → None

Generates a random channel matrix for all users.

Parameters

- **Nr** (*int* | *np.ndarray*) – Number of receive antennas of each user. If an integer is specified, all users will have that number of receive antennas.
- **Nt** (*int* | *np.ndarray*) – Number of transmit antennas of each user. If an integer is specified, all users will have that number of receive antennas.
- **K** (*int*) – Number of users.

re_seed() → None

Re-seed the channel and noise RandomState objects randomly.

If you want to specify the seed for each of them call the *set_channel_seed* and *set_noise_seed* methods and pass the desired seed for each of them.

set_channel_seed (*seed*: Optional[Union[*int*, List[*int*], *numpy.ndarray*]] = None) → None

Set the seed of the RandomState object used to generate the random elements of the channel (when self.randomize is called).

Parameters **seed** (None | *int* | *array_like*) – Random seed initializing the pseudo-random number generator. See np.random.RandomState help for more info.

set_noise_seed (*seed*: Optional[Union[*int*, List[*int*], *numpy.ndarray*]] = None) → None

Set the seed of the RandomState object used to generate the random noise elements (when the corrupt data function is called).

Parameters **seed** (None | *int* | *array_like*) – Random seed initializing the pseudo-random number generator. See np.random.RandomState help for more info.

set_pathloss (*pathloss_matrix*: Optional[*numpy.ndarray*] = None) → None

Set the path loss (IN LINEAR SCALE) from each transmitter to each receiver.

The path loss will be accounted when calling the *get_Hkl*, *get_Hk*, the *corrupt_concatenated_data* and the *corrupt_data* methods.

If you want to disable the path loss, set *pathloss_matrix* to None.

Parameters **pathloss_matrix** (*np.ndarray*) – A matrix with dimension “K x K”, where K is the number of users, with the path loss (IN LINEAR SCALE) from each transmitter (columns) to each receiver (rows). If you want to disable the path loss then set it to None.

Notes

Note that path loss is a power relation, which means that the channel coefficients will be multiplied by the square root of elements in *pathloss_matrix*.

set_post_filter (*filters*: *numpy.ndarray*) → *None*

Set the post-processing filters.

The post-processing filters will be applied to the data after if has been corrupted by the channel in either the *corrupt_data* or the *corrupt_concatenated_data* methods.

Parameters filters (*list*[*np.ndarray*] | *np.ndarray*) – The post processing filters of each user. This should be a list of 2D np arrays or a 1D np array of 2D np arrays.

class *pyphysim.channels.multiuser.MultiUserChannelMatrixExtInt*

Bases: *pyphysim.channels.multiuser.MultiUserChannelMatrix*

Very similar to the *MultiUserChannelMatrix* class, but the *MultiUserChannelMatrixExtInt* also includes the effect of an external interference.

This channel matrix can be seem as an concatenation of blocks (of non-uniform size) where each block is a channel from one transmitter to one receiver and the block size is equal to the number of receive antennas of the receiver times the number of transmit antennas of the transmitter. The difference compared with *MultiUserChannelMatrix* is that in the *MultiUserChannelMatrixExtInt* class the interference user counts as one more user, but with zero receive antennas.

For instance, in a 3-users scenario the block (1,0) corresponds to the channel between the transmit antennas of user 0 and the receive antennas of user 1 (indexing staring at zero). If the number of receive antennas and transmit antennas of the three users are [2, 4, 6] and [2, 3, 5], respectively, then the block (1,0) would have a dimension of 4x2. The external interference will count as one more block where the number of columns of this block corresponds to the rank of the external interference. If the external interference has a rank 2 then the complete channel matrix would look similar to the block structure below.

| | | | |
|-------|-------|-------|-------|
| 2 x 2 | 2 x 3 | 2 x 5 | 2 x 2 |
| 4 x 2 | 4 x 3 | 4 x 5 | 4 x 2 |
| 6 x 2 | 6 x 3 | 6 x 5 | 6 x 2 |

The methods from the *MultiUserChannelMatrix* class that makes sense were reimplemented here to include information regarding the external interference.

property H

Get method for the H property.

property H_no_ext_int

Get method for the H_no_ext_int property.

property K

Get method for the K property.

property Nr

Get method for the Nr property.

property Nt

Get method for the Nt property.

_calc JP_Bkl_cov_matrix_first_part (*F_all_users*: *numpy.ndarray*, *k*: *int*, *Rek*: *Num-berOrArray*) → *numpy.ndarray*

Calculates the first part in the equation of the Blk covariance matrix in equation (28) of [Cadambe2008] when joint process is employed.

The first part is given by

$$\sum_{j=1}^K \frac{P^{[j]}}{d^{[j]}} \sum_{d=1}^{d^{[j]}} \frac{[kj][j][j]^\dagger [kj]^\dagger}{*d *d} + Nk$$

Note that it only depends on the value of k .

Parameters

- **F_all_users** (*list* [*np.ndarray*] | *np.ndarray*) – The precoder of all users (already taking into account the transmit power). This can be either a 1D numpy array of numpy arrays or a list of numpy arrays.
- **k** (*int*) – Index of the desired user.
- **Rek** (*np.ndarray* | *float*) – Covariance matrix of the external interference plus noise.

Returns The first part in the equation of the Blk covariance matrix.

Return type *np.ndarray*

_calc_JP_Bkl_cov_matrix_second_part (*Fk*: *numpy.ndarray*, *k*: *int*, *l*: *int*) → *numpy.ndarray*

Calculates the second part in the equation of the Blk covariance matrix in equation (28) of [Cadambe2008] (note that it does not include the identity matrix).

The second part is given by

$$\frac{P^{[k]} [kk] [k] [k]^\dagger [kk]^\dagger}{d^{[k]} *l *l}$$

Parameters

- **Fk** (*np.ndarray*) – The precoder of the desired user.
- **k** (*int*) – Index of the desired user.
- **l** (*int*) – Index of the desired stream.

Returns **second_part** – Second part in equation (28) of [Cadambe2008].

Return type *np.ndarray*

_calc_JP_Q (*k*: *int*, *F_all_users*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the interference covariance matrix at the k -th receiver with a joint processing scheme (not including the covariance matrix of the external interference plus noise)

Parameters

- **k** (*int*) – Index of the desired receiver.
- **F_all_users** (*np.ndarray*) – The precoder of all users (already taking into account the transmit power). This is a 1D numpy array of 2D numpy array.

See also:

calc_JP_Q()

_calc_JP_SINR_k (*k*: *int*, *Fk*: *numpy.ndarray*, *Uk*: *numpy.ndarray*, *Bkl_all_l*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the SINR of all streams of user 'k'.

Parameters

- **Fk** (*np.ndarray*) – The precoder of user k.
- **Uk** (*np.ndarray*) – The receive filter of user k (before applying the conjugate transpose).

- **k** (*int*) – Index of the desired user.
- **Bkl_all_l** (*list*[*np.ndarray*] | *np.ndarray*) – A sequence (1D numpy array, a list, etc) of 2D numpy arrays corresponding to the Bkl matrices for all 'l's.

Returns The SINR for the different streams of user k.

Return type *np.ndarray*

static **_prepare_input_params** (*Nr*: *numpy.ndarray*, *Nt*: *numpy.ndarray*, *K*: *int*, *NtE*: *Iterable*[*int*]) → *Tuple*[*numpy.ndarray*, *numpy.ndarray*, *int*, *int*, *numpy.ndarray*]

Helper method used in the `init_from_channel_matrix` and `randomize` method definitions.

Parameters

- **Nr** (*np.ndarray*) – Number of antennas at each receiver.
- **Nt** (*np.ndarray*) – Number of antennas at each transmitter.
- **K** (*int*) – Number of transmit/receive pairs.
- **NtE** (*int* | *list*[*int*] | *np.ndarray*) – Number of transmit antennas of the external interference source(s). If *NtE* is an iterable, the number of external interference sources will be the `len(NtE)`.

Returns **output** – The tuple (`full_Nr`, `full_Nt`, `full_K`, `extIntK`, `extIntNt`).

Return type *tuple*

property **big_H_no_ext_int**

Get method for the `big_H_no_ext_int` property.

`big_H_no_ext_int` is similar to `big_H`, but does not include the last column(s) corresponding to the external interference channel.

calc JP_Q (*k*: *int*, *F_all_users*: *numpy.ndarray*, *pe*: *float* = 1.0) → *numpy.ndarray*

Calculates the interference covariance matrix at the *k*-th receiver with a joint processing scheme.

The interference covariance matrix at the *k*-th receiver, *k*, is given by

$$Q_k = \sum_{j=1, j \neq k}^K \frac{P_j}{N s_j} \mathbf{J}_j^H \mathbf{J}_k$$

where P_j is the transmit power of transmitter *j*, and $N s_j$ is the number of streams for user *j*.

Parameters

- **k** (*int*) – Index of the desired receiver.
- **F_all_users** (*list*[*np.ndarray*] | *np.ndarray*) – The precoder of all users (already taking into account the transmit power). This is a 1D numpy array of 2D numpy array.
- **pe** (*float*) – The power of the external interference source(s).

Returns **Qk** – The interference covariance matrix at receiver *k*.

Return type *np.ndarray*

calc JP_SINR (*F*: *numpy.ndarray*, *U*: *numpy.ndarray*, *pe*: *float* = 1.0) → *numpy.ndarray*

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the `noise_var` property.

Parameters

- **F** (*np.ndarray*) – The precoders of all users. This is a 1D numpy array of 2D numpy arrays.
- **U** (*np.ndarray*) – The receive filters of all users. This is a 1D numpy array of 2D numpy arrays.
- **pe** (*float*) – The external interference power.

Returns The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats).

Return type *np.ndarray*

calc_Q (*k: int, F_all_users: numpy.ndarray, pe: float = 1.0*) → *numpy.ndarray*

Calculates the interference covariance matrix at the *k*-th receiver.

The interference covariance matrix at the *k*-th receiver, *k*, is given by

$$Q_k = \sum_{j=1, j \neq k}^K \frac{P_j}{N s_j} \mathbf{F}_{kj}^H \mathbf{F}_{kj}$$

where P_j is the transmit power of transmitter *j*, and $N s_j$ is the number of streams for user *j*.

Parameters

- **k** (*int*) – Index of the desired receiver.
- **F_all_users** (*list[np.ndarray] | np.ndarray*) – The precoder of all users (already taking into account the transmit power). This should be either a list of numpy 2D arrays or a 1D numpy array of 2D numpy arrays.
- **pe** (*float*) – The power of the external interference source(s).

Returns **Qk** – The interference covariance matrix at receiver *k*.

Return type *np.ndarray*

calc_SINR (*F: numpy.ndarray, U: numpy.ndarray, pe: float = 1.0*) → *numpy.ndarray*

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the `noise_var` property.

Parameters

- **F** (*list[np.ndarray] | np.ndarray*) – The precoders of all users. This should be either a list of numpy 2D arrays or a 1D numpy array of 2D numpy arrays.
- **U** (*list[np.ndarray] | np.ndarray*) – The receive filters of all users. This should be either a list of numpy 2D arrays or a 1D numpy array of 2D numpy arrays.
- **pe** (*float*) – Power of the external interference source.

Returns **SINRs** – The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats)

Return type *np.ndarray*

calc_cov_matrix_extint_plus_noise (*pe: float = 1.0*) → *numpy.ndarray*

Calculates the covariance matrix of the external interference plus noise.

Parameters **pe** (*float, optional [default=1]*) – External interference power (in linear scale)

Returns **R_all_k** – Return a numpy array, where each element is the covariance matrix of the external interference plus noise at one receiver.

Return type *np.ndarray*

calc_cov_matrix_extint_without_noise (*pe: float = 1.0*) → *numpy.ndarray*

Calculates the covariance matrix of the external interference without include the noise.

Parameters *pe* (*float, optional*) – External interference power (in linear scale)

Returns *R_all_k* – Return a numpy array, where each element is the covariance matrix of the external interference at one receiver.

Return type *np.ndarray*

corrupt_concatenated_data (*data: numpy.ndarray*) → *numpy.ndarray*

Corrupt data passed through the channel.

If the *noise_var* member variable is not None then an white noise will also be added.

Parameters *data* (*np.ndarray*) – A bi-dimensional numpy array with the concatenated data of all transmitters as well as the data from all external interference sources. The dimension of data is $(\text{sum}(\text{self_Nt}) + \text{sum}(\text{self_extIntNt})) \times \text{NSymb}$. That is, the number of rows corresponds to the sum of the number of transmit antennas of all users and external interference sources and the number of columns correspond to the number of transmitted symbols.

Returns *output* – A bi-dimension numpy array where the number of rows corresponds to the sum of the number of receive antennas of all users and the number of columns correspond to the number of transmitted symbols.

Return type *np.ndarray*

corrupt_data (*data: numpy.ndarray, ext_int_data: numpy.ndarray*) → *numpy.ndarray*

Corrupt data passed through the channel.

If the *noise_var* member variable is not None then an white noise will also be added.

Parameters

- **data** (*np.ndarray*) – An array of numpy matrices with the data of the multiple users. The *k*-th element in *data* is a numpy array with dimension $\text{Nt_k} \times \text{NSymb}$, where *Nt_k* is the number of transmit antennas of the *k*-th user and *NSymb* is the number of transmitted symbols.
- **ext_int_data** (*list[np.ndarray] | np.ndarray*) – An array of numpy matrices with the data of the external interference sources. The *l*-th element is the data transmitted by the *l*-th external interference source, which must have a dimension of $\text{NtEl} \times \text{NSymb}$, where *NtEl* is the number of transmit antennas of the *l*-th external interference source.

Returns *output* – A numpy array where each element contains the received data (a 2D numpy array) of a user.

Return type *np.ndarray*

property extIntK

Get method for the *extIntK* property.

property extIntNt

Get method for the *extIntNt* property.

get_Hk_with_ext_int (*k: int*) → *numpy.ndarray*

Get the channel from all transmitters (including the external interference sources) to receiver *k*.

This method is essentially the same as the *get_Hk* method.

Parameters *k* (*int*) – Receiving user.

Returns *channel_k* – Channel from all transmitters to receiver *k*.

Return type np.ndarray

See also:

`get_Hk1()`, `get_Hk()`, `get_Hk_without_ext_int()`

Examples

```
>>> multiH = MultiUserChannelMatrixExtInt()
>>> H = np.reshape(np.r_[0:20], [4,5])
>>> Nt = np.array([2, 2])
>>> Nr = np.array([2, 2])
>>> NextInt = np.array([1])
>>> multiH.init_from_channel_matrix(H, Nr, Nt, 2, 1)
>>> # Note that the last column of multiH.big_H corresponds to the
>>> # external interference source
>>> print(multiH.big_H)
[[ 0  1  2  3  4]
 [ 5  6  7  8  9]
 [10 11 12 13 14]
 [15 16 17 18 19]]
>>> print(multiH.get_Hk_with_ext_int(0))
[[0 1 2 3 4]
 [5 6 7 8 9]]
>>> print(multiH.get_Hk_with_ext_int(1))
[[10 11 12 13 14]
 [15 16 17 18 19]]
```

get_Hk_without_ext_int (*k*: int) → numpy.ndarray

Get the channel from all transmitters (without including the external interference sources) to receiver *k*.

Parameters *k* (int) – Receiving user.

Returns **channel_k** – Channel from all transmitters to receiver *k* (2D numpy array).

Return type np.ndarray

See also:

`get_Hk1()`, `get_Hk()`, `get_Hk_with_ext_int()`

Examples

```
>>> multiH = MultiUserChannelMatrixExtInt()
>>> H = np.reshape(np.r_[0:20], [4,5])
>>> Nt = np.array([2, 2])
>>> Nr = np.array([2, 2])
>>> NextInt = np.array([1])
>>> multiH.init_from_channel_matrix(H, Nr, Nt, 2, 1)
>>> # Note that the last column of multiH.big_H corresponds to the
>>> # external interference source
>>> print(multiH.big_H)
[[ 0  1  2  3  4]
 [ 5  6  7  8  9]
 [10 11 12 13 14]
 [15 16 17 18 19]]
>>> print(multiH.get_Hk_without_ext_int(0))
```

(continues on next page)

(continued from previous page)

```

[[0 1 2 3]
 [5 6 7 8]]
>>> print(multiH.get_Hk_without_ext_int(1))
[[10 11 12 13]
 [15 16 17 18]]

```

init_from_channel_matrix (*channel_matrix*: *numpy.ndarray*, *Nr*: *numpy.ndarray*, *Nt*: *numpy.ndarray*, *K*: *int*, *NtE*: *Iterable[int]*) → *None*

Initializes the multiuser channel matrix from the given *channel_matrix*.

Note that *channel_matrix* must also include the channel terms for the external interference, which must be the last *NtE* columns of *channel_matrix*. The number of rows in *channel_matrix* must be equal to $\text{np.sum}(\text{Nr})$, while the number of columns must be $\text{np.sum}(\text{Nt}) + \text{NtE}$.

Parameters

- **channel_matrix** (*np.ndarray*) – A matrix concatenating the channel of all transmitters (including the external interference sources) to all receivers.
- **Nr** (*np.ndarray*) – Number of antennas at each receiver.
- **Nt** (*np.ndarray*) – Number of antennas at each transmitter.
- **K** (*int*) – Number of transmit/receive pairs.
- **NtE** (*int* | *list[int]* | *np.ndarray*) – Number of transmit antennas of the external interference source(s). If *NtE* is an iterable, the number of external interference sources will be the $\text{len}(\text{NtE})$.

Raises **ValueError** – If the arguments are invalid.

randomize (*Nr*: *Union[numpy.ndarray, int]*, *Nt*: *Union[numpy.ndarray, int]*, *K*: *int*, *NtE*: *Iterable[int]*) → *None*

Generates a random channel matrix for all users as well as for the external interference source(s).

Parameters

- **Nr** (*int* | *np.ndarray*) – Number of receive antennas of each user. If an integer is specified, all users will have that number of receive antennas.
- **Nt** (*int* | *np.ndarray*) – Number of transmit antennas of each user. If an integer is specified, all users will have that number of receive antennas.
- **K** (*int*) – Number of users.
- **NtE** (*int* | *list[int]* | *np.ndarray*) – Number of transmit antennas of the external interference source(s). If *NtE* is an iterable, the number of external interference sources will be the $\text{len}(\text{NtE})$.

set_pathloss (*pathloss_matrix*: *Optional[numpy.ndarray]* = *None*, *ext_int_pathloss*: *Optional[numpy.ndarray]* = *None*) → *None*

Set the path loss (IN LINEAR SCALE) from each transmitter to each receiver, as well as the path loss from the external interference source(s) to each receiver.

The path loss will be accounted when calling the `get_Hkl`, `get_Hk`, the `corrupt_concatenated_data` and the `corrupt_data` methods.

Note that path loss is a power relation, which means that the channel coefficients will be multiplied by the square root of elements in *pathloss_matrix*.

If you want to disable the path loss, set *pathloss_matrix* to *None*.

Parameters

- **pathloss_matrix** (*np.ndarray*) – A matrix with dimension “K x K”, where K is the number of users, with the path loss (IN LINEAR SCALE) from each transmitter (columns) to each receiver (rows). If you want to disable the path loss then set it to None.
- **ext_int_pathloss** : 2D numpy array The path loss from each interference source to each receiver. The number of rows of ext_int_pathloss must be equal to the number of receives, while the number of columns must be equal to the number of external interference sources.
- **ext_int_pathloss** (*np.ndarray*) – The external interference path loss.

pyphysim.channels.noise module

pyphysim.channels.noise.**calc_thermal_noise_power_dBm** (*T: float, delta_f: float*) → *float*

Calculate the thermal noise power (in dBm) for the given room temperature *T* (in C°) and bandwidth *delta_f* (in Hz).

Parameters

- **T** (*float*) – Room temperature in Cesium degrees.
- **delta_f** (*float*) – Bandwidth in Hz.

Returns **noise_var** – The noise power.

Return type *float*

pyphysim.channels.pathloss module

Implement classes for several Path loss models.

The *PathLossBase* class implements the common code to every path loss model and only two methods need to be implemented in subclasses: the *PathLossBase.which_distance_dB()* and the *PathLossBase._calc_deterministic_path_loss_dB()* methods. However, instead of inheriting directly from *PathLossBase*, inherit from either *PathLossIndoorBase* or *PathLossOutdoorBase*.

The most common usage of a path loss class is to instantiate an object of the desired path loss model and then call the **calc_path_loss_dB** or the **calc_path_loss** methods to actually calculate the path loss.

class pyphysim.channels.pathloss.**PathLoss3GPP1**

Bases: *pyphysim.channels.pathloss.PathLossGeneral*

Class to calculate the Path Loss according to the model from 3GPP (scenario 1). That is, the Path Loss (in dB) is equal to

$$PL = 128.1 + 37.6 * \log_{10}(d)$$

This model is valid for LTE assumptions and at 2GHz frequency, where the distance is in Km.

Examples

Determining the path loss in the free space for a distance of 1Km (without considering shadowing).

```
>>> pl = PathLoss3GPP1()
>>> pl.calc_path_loss(1)           # linear scale
1.5488166189124858e-13
>>> pl.calc_path_loss_dB(1)       # log scale
128.1
```

Determining the distance (in Km) that yields a path loss of 130dB.

```
>>> pl.which_distance_dB(130)
1.1233935211892188
```

`__repr_latex__()` → `str`

Get a Latex representation of the PathLossFreeSpace class.

This is useful for representing the path loss object in an IPython notebook.

Returns The Latex representation of the path loss object.

Return type `str`

class `pyphysim.channels.pathloss.PathLossBase`

Bases: `object`

Base class for the different Path Loss models.

The common interface for the path loss classes is provided by the `calc_path_loss_dB()` or the `calc_path_loss()` methods to actually calculate the path loss for a given distance, as well as the `which_distance_dB()` or `which_distance()` methods to determine the distance that yields the given path loss.

Each subclass of PathLossBase NEED TO IMPLEMENT only the `which_distance_dB()` and the `_calc_deterministic_path_loss_dB()` functions.

If the `use_shadow_bool` attribute is set to True then calling `calc_path_loss_dB()` or `calc_path_loss()` will take the shadowing specified in the `sigma_shadow` attribute into account. However, shadowing is not taken into account in the `which_distance_dB()` and `which_distance()` functions, regardless of the value of the `use_shadow_bool` variable.

sigma_shadow

The shadowing (in dB)

Type `int`

use_shadow_bool

If True then shadowing will be used.

Type `bool`

handle_small_distances_bool

If this is True then any negative path loss (in dB) that appears because a distance is too small will be considered as 0dB. If this is False then an exception will be raised instead.

Type `bool`

__TYPE = 'base'

abstract `_calc_deterministic_path_loss_dB(d: NumberOrArray, **kwargs: Any) → NumberOrArray`

Calculates the Path Loss (in dB) for a given distance (in Km) without including the shadowing.

Parameters

- `d(float | np.ndarray)` – Distance (in Km)
- `kwargs(dict, optional)` – Optional parameters for use in subclasses if required.

Other Parameters `kwargs(dict)` – Additional keywords that might be necessary in a subclass.

Returns `PL` – Path loss (in dB).

Return type `float | np.ndarray`

Raises `NotImplementedError` – If the `_calc_deterministic_path_loss_dB` method of the `PathLossBase` class is called.

`_plot_deterministic_path_loss_in_dB_impl` (*d*: `numpy.ndarray`, *ax*: `Optional[Any]` = `None`, *extra_args*: `Optional[Any]` = `None`, *distance_unit*: `str` = `'Km'`) → `None`

Plot the path loss (in dB) for the distance values in *d* (in Km).

Parameters

- ***d*** (`np.ndarray`) – Distance (in correct unit)
- ***ax*** (*A matplotlib ax, optional*) – The ax where the path loss will be plotted. If not provided, a new figure (and ax) will be created.
- ***extra_args*** (*dict*) – Extra arguments that will be passed to the `ax.plot` command as `**extra_args` (see Matplotlib documentation). Ex: `{‘label’: ‘curve name’, ‘linewidth’: 2}`

`calc_path_loss` (*d*: `NumberOrArray`, ***kargs*: `Any`) → `NumberOrArray`

Calculates the path loss (linear scale) for a given distance (in Km).

Parameters

- ***d*** (`float` | `np.ndarray`) – Distance (in Km)
- ***kargs*** (*dict*) – Extra named parameters. This is used in subclasses for extra parameters for the path loss calculation.

Other Parameters *kwargs* (*dict*) – Additional keywords that might be necessary in a subclass.

Returns **pl** – Path loss (in linear scale) for the given distance(s).

Return type `float` | `np.ndarray`

`calc_path_loss_dB` (*d*: `NumberOrArray`, ***kargs*: `Any`) → `NumberOrArray`

Calculates the Path Loss (in dB) for a given distance (in Km).

Note that the returned value is positive, but should be understood as “a loss”.

Parameters

- ***d*** (`float` | `np.ndarray`) – Distance (in Km)
- ***kargs*** (*dict*) – Optional parameters for use in subclasses if required.

Other Parameters *kwargs* (*dict*) – Additional keywords that might be necessary in a subclass.

Returns **PL** – Path loss (in dB) for the given distance(s).

Return type `float` | `np.ndarray`

`plot_deterministic_path_loss_in_dB` (*d*: `numpy.ndarray`, *ax*: `Optional[Any]` = `None`, *extra_args*: `Optional[Any]` = `None`) → `None`

Plot the path loss (in dB) for the distance values in *d* (in Km).

Parameters

- ***d*** (`np.ndarray`) – Distance (in Km)
- ***ax*** (*A matplotlib ax, optional*) – The ax where the path loss will be plotted. If not provided, a new figure (and ax) will be created.
- ***extra_args*** (*dict*) – Extra arguments that will be passed to the `ax.plot` command as `**extra_args` (see Matplotlib documentation). Ex: `{‘label’: ‘curve name’, ‘linewidth’: 2}`

property type

Get method for the type property.

which_distance (*pl*: *NumberOrArray*) → *NumberOrArray*

Calculates the required distance (in Km) to achieve the given path loss. It is the inverse of the `calc_path_loss` function.

Parameters *pl* (*float* | *np.ndarray*) – Path loss (in linear scale).

Returns *d* – Distance(s) that will yield the path loss *pl*.

Return type *float* | *np.ndarray*

abstract which_distance_dB (*PL*: *NumberOrArray*) → *NumberOrArray*

Calculates the distance that yields the given path loss (in dB).

Parameters *PL* (*float* | *np.ndarray*) – Path Loss (in dB)

Returns *d* – Distance to get the desired path loss *PL*.

Return type *float* | *np.ndarray*

Raises **NotImplementedError** – If the `which_distance_dB` method of the `PathLossBase` class is called.

class `pyphysim.channels.pathloss.PathLossFreeSpace` (*n*: *float* = 2.0, *fc*: *float* = 900.0)

Bases: `pyphysim.channels.pathloss.PathLossGeneral`

Class to calculate the Path Loss in the free space.

The common interface for the path loss classes is provided by the `PathLossOutdoorBase.calc_path_loss_dB()` or the `PathLossOutdoorBase.calc_path_loss()` methods to actually calculate the path loss for a given distance, as well as the `PathLossGeneral.which_distance_dB()` or `PathLossBase.which_distance()` methods to determine the distance that yields the given path loss.

For the path loss in free space you also need to set the *n* variable, corresponding to the path loss coefficient, and the *fc* variable, corresponding to the frequency. The *n* variable defaults to 2 and *fc* defaults to 900 (that is, 900MHz).

The path loss (in dB) in free space is calculated as:

$$PL = 10n(\log_{10}(d) + \log_{10}(fc * 1e6) - 4.3779113907)$$

Likewise, the `PathLossGeneral.which_distance_dB()` function calculates the value of

$$10^{(PL/(10n) - \log_{10}(fc) + 4.377911390697565)}$$

Parameters

- **n** (*float*) – Path loss exponent.
- **fc** (*float*) – Central carrier frequency (in MHz).

Examples

Determining the path loss in the free space for a distance of 1Km (without considering shadowing).

```
>>> pl = PathLossFreeSpace()
>>> pl.calc_path_loss(1)           # linear scale
7.036193308495632e-10
>>> pl.calc_path_loss_dB(1)       # log scale
91.5266223748352
```

Determining the distance (in Km) that yields a path loss of 90dB.

```
>>> pl.which_distance_dB(90)
0.8388202017414481
```

static `_calculate_C_from_fc_and_n` (*fc: float, n: float*) → *float*

Calculate the value of the constant *C* for the frequency value *fc* and path loss exponent *n*.

Parameters

- **fc** (*float*) – Central carrier frequency (in MHz)
- **n** (*float*) – Path loss exponent

Returns *C* – Constant *C* for the Free Space path loss model for the given frequency and path loss exponent.

Return type *float*

repr_latex () → *str*

Get a Latex representation of the PathLossFreeSpace class.

This is useful for representing the path loss object in an IPython notebook.

Returns The Latex representation of the path loss object.

Return type *str*

property *fc*

Get the central carrier frequency.

Returns The central carrier frequency.

Return type *float*

property *n*

Get method for the *n* property.

Returns The path loss exponent.

Return type *float*

class `pyphysim.channels.pathloss.PathLossGeneral` (*n: float, C: float*)

Bases: `pyphysim.channels.pathloss.PathLossOutdoorBase`

Class to calculate the path loss given the path loss for a reference distance.

In its simplest form, the path loss can be calculated using the formula

$$PL = 10n \log_{10}(d) + C$$

where *PL* is in dB, *n* is the path loss exponent (usually in the range of 2 to 4) and *d* is the distance between the transmitter and the receiver.

Parameters

- **n** (*float*) – The path loss exponent.
- **C** (*float*) – The constant *C* in the path loss formula.

_calc_deterministic_path_loss_dB (*d: NumberOrArray, **kargs: Any*) → *NumberOrArray*

Calculates the Path Loss (in dB) for a given distance (in Km).

Note that the returned value is positive, but should be understood as “a loss”.

For *d* in Km and *self.fc* in MHz, the free space Path Loss is given by

$$PL = 10n \log_{10}(d) + C$$

Parameters *d* (*float* | *np.ndarray*) – Distance (in Km).

Returns *pl_dB* – Path loss in dB.

Return type *float* | *np.ndarray*

`__get_latex_repr()` → *str*

Get the Latex representation (equation) for the PathLossGeneral class.

The general equation is given by

$$PL = 10n \log_{10}(d) + C$$

Returns The Latex representation of the path loss object.

Return type *str*

`__repr_latex__()` → *str*

Get a Latex representation of the PathLossGeneral class.

This is useful for representing the path loss object in an IPython notebook.

Returns The Latex representation of the path loss object.

Return type *str*

`which_distance_dB(PL: NumberOrArray)` → *NumberOrArray*

Calculates the required distance (in Km) to achieve the given path loss (in dB).

It is the inverse of the `calc_path_loss` function.

$$10^{(PL/(10n)-C)}$$

`d = obj.whichDistance(dB2Linear(-PL));`

Parameters *PL* (*float* | *np.ndarray*) – Path Loss (in dB).

Returns *d* – Distance (in Km).

Return type *float* | *np.ndarray*

`class pyphysim.channels.pathloss.PathLossIndoorBase`

Bases: *pyphysim.channels.pathloss.PathLossBase*

Base class for the different Indoor Path Loss models.

The common interface for the path loss classes is provided by the `calc_path_loss_dB()` or the `calc_path_loss()` methods to actually calculate the path loss for a given distance, as well as the `which_distance_dB()` or `which_distance` methods to determine the distance that yields the given path loss.

Each subclass of PathLossBase NEED TO IMPLEMENT only the `which_distance_dB()` and the `__calc_deterministic_path_loss_dB()` functions.

If the `use_shadow_bool` is set to True then calling `calc_path_loss_dB()` or `calc_path_loss()` will take the shadowing specified in the `sigma_shadow` variable into account. However, shadowing is not taken into account in the `which_distance_dB()` and `which_distance()` functions, regardless of the value of the `use_shadow_bool` variable.

`__TYPE = 'indoor'`

`abstract __calc_deterministic_path_loss_dB(d: NumberOrArray, **kargs: Any) → NumberOrArray`

Calculates the Path Loss (in dB) for a given distance (in meters) without including the shadowing.

Parameters *d* (*float* | *np.ndarray*) – Distance (in meters)

Other Parameters **kwargs** (*dict*) – Additional keywords that might be necessary in a subclass.

Returns **PL** – The calculated path loss.

Return type float | np.ndarray

Raises **NotImplementedError** – If the `_calc_deterministic_path_loss_dB` method of the `PathLossBase` class is called.

calc_path_loss (*d: NumberOrArray, **kwargs: Any*) → NumberOrArray

Calculates the path loss (linear scale) for a given distance (in meters).

Parameters

- **d** (*float | np.ndarray*) – Distance (in meters)
- **kwargs** (*dict*) – Additional keywords that might be necessary in a subclass.

Returns **pl** – Path loss (in linear scale) for the given distance(s).

Return type float | np.ndarray

calc_path_loss_dB (*d: NumberOrArray, **kwargs: Any*) → NumberOrArray

Calculates the Path Loss (in dB) for a given distance (in meters).

Note that the returned value is positive, but should be understood as “a loss”.

Parameters

- **d** (*float | np.ndarray*) – Distance (in meters)
- **kwargs** (*dict*) – Additional keywords that might be necessary in a subclass.

Returns **PL** – Path loss (in dB) for the given distance(s).

Return type float | np.ndarray

plot_deterministic_path_loss_in_dB (*d: NumberOrArray, ax: Optional[Any] = None, extra_args: Optional[Any] = None*) → None

Plot the path loss (in dB) for the distance values in *d* (in meters).

Parameters

- **d** (*np.ndarray*) – Distance (in meters)
- **ax** (*A matplotlib ax, optional*) – The ax where the path loss will be plotted. If not provided, a new figure (and ax) will be created.
- **extra_args** (*dict*) – Extra arguments that will be passed to the `ax.plot` command as `**extra_args` (see Matplotlib documentation). Ex: `{‘label’: ‘curve name’, ‘linewidth’: 2}`

which_distance (*pl: NumberOrArray*) → NumberOrArray

Calculates the required distance (in meters) to achieve the given path loss. It is the inverse of the `calc_path_loss` function.

Parameters **pl** (*float | np.ndarray*) – Path loss (in linear scale).

Returns **d** – Distance(s) that will yield the path loss *pl*.

Return type float | np.ndarray

abstract which_distance_dB (*PL: NumberOrArray*) → NumberOrArray

Calculates the distance that yields the given path loss (in dB).

Parameters **PL** (*float | np.ndarray*) – Path Loss (in dB)

Returns **d** – The distance to yield the given path loss.

Return type float | np.ndarray

Raises `NotImplementedError` – If the `which_distance_dB` method of the `PathLossBase` class is called.

class `pyphysim.channels.pathloss.PathLossMetisPS7` (*fc*: float = 900.0)

Bases: `pyphysim.channels.pathloss.PathLossIndoorBase`

Class to calculate the Path Loss (indoor) according to the model described for the Propagation Scenario (PS) 7 of the METIS project.

This model is an indoor-2-indoor model.

`_calc_PS7_path_loss_dB_LOS_same_floor` (*d*: NumberOrArray) → NumberOrArray

Calculate the deterministic path loss according to the Propagation Scenario (PS) 7 of the METIS project for the LOS case.

The path loss (in dB) is calculated as

$$PL = A \log_{10}(d) + B + C \log_{10}(f_c/5)$$

The distance d is in meters, while the frequency f_c is in GHz.

The other variables (NLOS case) are:

$$A = 18.7B = 46.8, C = 20$$

where n_w is the number of walls between the transmitter and receiver.

Parameters *d* (float | np.ndarray) – Distance (in meters).

Returns *pl_dB* – Path loss in dB.

Return type float | np.ndarray

`_calc_PS7_path_loss_dB_NLOS_same_floor` (*d*: NumberOrArray, *num_walls*: int = 1) → NumberOrArray

Calculate the deterministic path loss according to the Propagation Scenario (PS) 7 of the METIS project for the NLOS case.

The path loss (in dB) is calculated as

$$PL = A \log_{10}(d) + B + C \log_{10}(f_c/5) + X$$

The distance d is in meters, while the frequency f_c is in Hz.

The other variables (NLOS case) are:

$$A = 36.8B = 43.8, C = 20, X = 5(n_w - 1)$$

where n_w is the number of walls between the transmitter and receiver.

Parameters

- *d* (float | np.ndarray) – Distance (in meters).
- *num_walls* (int | np.ndarray) – Number of walls between the transmitter and the receiver. If it is an int array it must have the same dimension as d .

Returns *pl_dB* – Path loss in dB.

Return type float | np.ndarray

`_calc_PS7_path_loss_dB_same_floor` (*d*: NumberOrArray, *num_walls*: *int* = 0) → NumberOrArray

Calculate the deterministic path loss according to the Propagation Scenario (PS) 7 of the METIS project.

The path loss (in dB) is calculated as

$$PL = A \log_{10}(d) + B + C \log_{10}(f_c/5) + X$$

The distance d is in meters, while the frequency f_c is in GHz. Na others variables a different for the LOS and NLOS cases.

For the LOS case we have:

$$A = 18.7, B = 46.8, C = 20, X = 0$$

For the NLOS case we have:

$$A = 36.8, B = 43.8, C = 20, X = 5(n_w - 1)$$

where n_w is the number of walls between the transmitter and receiver.

Parameters

- **`d`** (*float* | *np.ndarray*) – Distance (in meters).
- **`num_walls`** (*int* | *np.ndarray*) – Indicates how many walls the signal has to pass. If `num_walls` is zero, then Line-of-Sight parameters are used. If it is greater than zero then Non-Sign-of-Sight parameters are used. If `num_walls` is a numpy array then it must have the same dimension as d and it then specifies the number of walls for each individual value of d

Returns **`pl_dB`** – Path loss in dB.

Return type *float* | *np.ndarray*

`_calc_deterministic_path_loss_dB` (*d*: NumberOrArray, *num_walls*: *int* = 0) → NumberOrArray

Calculates the Path Loss (in dB) for a given distance (in meters) without including the shadowing.

Parameters

- **`d`** (*float* | *np.ndarray*) – Distance (in meters)
- **`num_walls`** (*int* | *np.ndarray*) – Number of walls between the transmitter and the receiver. If it is an int array it must have the same dimension as d .

Returns **`PL`** – The calculated path loss.

Return type *float* | *np.ndarray*

`_repr_latex_` () → *str*

Get a Latex representation of the PathLossMetisPS7 class.

This is useful for representing the path loss object in an IPython notebook.

Returns The Latex representation of the path loss object.

Return type *str*

property **`fc`**

Get the central carrier frequency.

Returns The central carrier frequency.

Return type *float*

static get_latex_repr (*num_walls: Optional[int] = None*) → str

Get the Latex representation (equation) for the PathLossGeneral class.

The general equation is given by

$$PL = A \log_{10}(d) + B + C \log_{10}(f_c/5) + X$$

where the parameters A, B, C and X depend on the number of walls.

Parameters *num_walls* (*int*, *None*) – Number of walls. LOS is used if it is 0 and NLOS is used if it is greater than zero. If it is None, then letters are used instead of numeric values.

Returns The Latex representation (equation) for the PathLossGeneral class.

Return type str

which_distance_dB (*PL: NumberOrArray*) → NumberOrArray

Calculates the distance that yields the given path loss (in dB).

Parameters *PL* (*float* | *np.ndarray*) – Path Loss (in dB)

Returns *d* – The distance to yield the given path loss.

Return type float | np.ndarray

Raises **NotImplementedError** – If the which_distance_dB method of the PathLossBase class is called.

class pyphysim.channels.pathloss.**PathLossOkomuraHata**

Bases: *pyphysim.channels.pathloss.PathLossOutdoorBase*

Class to calculate the Path Loss according to the Okomura Hata model.

The exact formula depend on the area type, but in general the path loss is given by (in dB):

$$PL = 69.55 + 26.16 * \log(fc) - 13.82 * \log(h_{bs}) - a(h_{ms}) + (44.9 - 6.55 \log(h_{bs})) \log(d) - K$$

The term $a(h_{ms})$ is the mobile station correction factor (see *_calc_mobile_antenna_height_correction_factor()*)

The term K is a correction factor that depends on the area type (see *_calc_K()*).

The possible area types are (in ascending order): ‘open’, ‘suburban’, ‘medium city’ and ‘large city’.

_calc_K() → float

Calculates the “‘medium city’/‘suburban’/‘open area’” correction factor.

Returns *K* – The correction factor “K”.

Return type float

_calc_deterministic_path_loss_dB (*d: NumberOrArray*, ***kargs: Any*) → NumberOrArray

Calculates the Path Loss (in dB) for a given distance (in Km).

Note that the returned value is positive, but should be understood as “a loss”.

For *d* in Km and *self.fc* in Hz, the free space Path Loss is given by

$$PL = 10n(\log_{10}(d) + \log_{10}(f) - 4.3779113907)$$

Parameters *d* (*float* | *np.ndarray*) – Distance (in Km). Can be between 1km and 20Km.

Returns *PL* – Path loss in dB.

Return type float | np.ndarray

`_calc_mobile_antenna_height_correction_factor()` → float

Calculates the mobile antenna height correction factor.

This factor is strongly impacted by surrounding buildings and is refined according to city sizes. For all area types, except ‘large city’, the mobile antenna correction factor is given by

$$a(h_{ms}) = (1.1 \log(f) - 0.7)h_{ms} - 1.56 \log(f) + 0.8$$

For the ‘large city’ area type, the mobile antenna height correction is given by

$$a(h_{ms}) = 3.2(\log(11.75 * h_{ms})^2) - 4.97$$

if the frequency is greater than 300MHz, or

$$a(h_{ms}) = 8.29(\log(1.54h_{ms}))^2 - 1.10$$

if the frequency is lower than 300MHz (and greater than 150MHz where the Okomura Hata model is valid).

Returns The mobile antenna height correction.

Return type float

property area_type

Get method for the area_type property.

property fc

Get the central carrier frequency.

Returns The central carrier frequency.

Return type float

property hbs

Get the height of the Base Station property.

Returns Height of the Base Station (in meters).

Return type float

property hms

Get the height of the Mobile Station property.

Returns Height of the Mobile Station (in meters).

Return type float

which_distance_dB (PL: NumberOrArray) → NumberOrArray

Calculates the required distance (in Km) to achieve the given path loss (in dB).

It is the inverse of the calc_path_loss function.

Parameters PL (float | np.ndarray) – Path loss (in dB).

Returns d – Distance (in Km).

Return type float | np.ndarray

class pyphysim.channels.pathloss.PathLossOutdoorBase

Bases: `pyphysim.channels.pathloss.PathLossBase`

Base class for the different Outdoor Path Loss models.

The common interface for the path loss classes is provided by the `calc_path_loss_dB()` or the `calc_path_loss()` methods to actually calculate the path loss for a given distance, as well as the

`which_distance_dB()` or `PathLossBase.which_distance()` methods to determine the distance that yields the given path loss.

Each subclass of `PathLossBase` NEED TO IMPLEMENT only the `which_distance_dB()` and the `_calc_deterministic_path_loss_dB()` functions.

If the `use_shadow_bool` is set to `True` then calling `calc_path_loss_dB()` or `calc_path_loss()` will take the shadowing specified in the `sigma_shadow` variable into account. However, shadowing is not taken into account in the `which_distance_dB()` and `PathLossBase.which_distance()` functions, regardless of the value of the `use_shadow_bool` variable.

_TYPE = 'outdoor'

abstract _calc_deterministic_path_loss_dB (*d: NumberOrArray, **kargs: Any*) → NumberOrArray

Calculates the Path Loss (in dB) for a given distance (in Km) without including the shadowing.

Parameters *d* (*float | np.ndarray*) – Distance (in Km)

Other Parameters *kargs* (*dict*) – Additional keywords that might be necessary in a subclass.

Returns *PL* – The calculated path loss (in dB).

Return type *float | np.ndarray*

Raises `NotImplementedError` – If the `_calc_deterministic_path_loss_dB` method of the `PathLossBase` class is called.

calc_path_loss (*d: NumberOrArray, **kargs: Any*) → NumberOrArray

Calculates the path loss (linear scale) for a given distance (in Km).

Parameters

- *d* (*float | np.ndarray | list[float]*) – Distance (in Km)
- *kargs* (*dict*) – Additional keywords that might be necessary in a subclass.

Returns *pl* – Path loss (in linear scale) for the given distance(s).

Return type *float | np.ndarray*

calc_path_loss_dB (*d: NumberOrArray, **kargs: Any*) → NumberOrArray

Calculates the Path Loss (in dB) for a given distance (in Km).

Note that the returned value is positive, but should be understood as “a loss”.

Parameters

- *d* (*float | np.ndarray | list[float]*) – Distance (in Km)
- *kargs* (*dict*) – Additional keywords that might be necessary in a subclass.

Returns *PL* – Path loss (in dB) for the given distance(s).

Return type *float | np.ndarray*

plot_deterministic_path_loss_in_dB (*d: NumberOrArray, ax: Optional[Any] = None, extra_args: Optional[Any] = None*) → `None`

Plot the path loss (in dB) for the distance values in *d* (in Km).

Parameters

- *d* (*np.ndarray*) – Distance (in Km)
- *ax* (*A matplotlib ax, optional*) – The *ax* where the path loss will be plotted. If not provided, a new figure (and *ax*) will be created.

- **extra_args** (*dict*) – Extra arguments that will be passed to the `ax.plot` command as `**extra_args` (see Matplotlib documentation). Ex: `{‘label’: ‘curve name’, ‘linewidth’: 2}`

abstract which_distance_dB (*PL: NumberOrArray*) → *NumberOrArray*

Calculates the distance that yields the given path loss (in dB).

Parameters **PL** (*float | np.ndarray*) – Path Loss (in dB)

Returns **d** – The distance that yields the given path loss.

Return type *float | np.ndarray*

Raises **NotImplementedError** – If the `which_distance_dB` method of the `PathLossBase` class is called.

pyphysim.channels.singleuser module

Module containing single user channels.

class `pyphysim.channels.singleuser.SuChannel` (*fading_generator: Optional[Union[pyphysim.channels.fading_generators.JakesSampleGenerator, pyphysim.channels.fading_generators.RayleighSampleGenerator]] = None, channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile] = None, tap_powers_dB: Optional[numpy.ndarray] = None, tap_delays: Optional[numpy.ndarray] = None, Ts: Optional[float] = None*)

Bases: `object`

Single User channel corresponding to a Tapped Delay Line channel model, which corresponds to a multipath channel. You can use a single tap in order to get a flat fading channel.

You can create a new `SuChannel` object either specifying the channel profile or specifying both the channel tap powers and delays. If only the `fading_generator` is specified then a single tap with unitary power and delay zero will be assumed, which corresponds to a flat fading channel model.

Parameters

- **fading_generator** (*FadingGenerator*) – The instance of a fading generator in the `fading_generators` module. It should be a subclass of `FadingSampleGenerator`. The fading generator will be used to generate the channel samples. If not provided then `RayleighSampleGenerator` will be used
- **channel_profile** (*fading.TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- **tap_powers_dB** (*np.ndarray*) – The powers of each tap (in dB). Dimension: $L \times 1$
Note: The power of each tap will be a negative number (in dB).
- **tap_delays** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: $L \times 1$
- **Ts** (*float, optional*) – The sampling interval.

property channel_profile

Return the channel profile.

Returns The channel profile.

Return type *fading.TdlChannelProfile*

corrupt_data (*signal*: *numpy.ndarray*) → *numpy.ndarray*

Transmit the signal through the TDL channel.

Parameters **signal** (*np.ndarray*) – The signal to be transmitted.

Returns The received signal after transmission through the TDL channel.

Return type *np.ndarray*

corrupt_data_in_freq_domain (*signal*: *numpy.ndarray*, *fft_size*: *int*, *carrier_indexes*: *Optional[Union[numpy.ndarray, List[int], slice]] = None*) → *numpy.ndarray*

Transmit the signal through the TDL channel, but in the frequency domain.

This is ROUGHLY equivalent to modulating *signal* with OFDM using *fft_size* subcarriers, transmitting through a regular TdlChannel, and then demodulating with OFDM to recover the received signal.

One important difference is that here the channel is considered constant during the transmission of *fft_size* elements in *signal*, and then it is varied by the equivalent of the variation for that number of elements. That is, the channel is block static.

Parameters

- **signal** (*np.ndarray*) – The signal to be transmitted.
- **fft_size** (*int*) – The size of the Fourier transform to get the frequency response.
- **carrier_indexes** (*slice* | *np.ndarray*) – The indexes of the subcarriers where signal is to be transmitted. If it is None assume all subcarriers will be used. This can be a slice object or a numpy array of integers.

Returns The received signal after transmission through the TDL channel

Return type *np.ndarray*

get_last_impulse_response () → *pyphysim.channels.fading.TdlImpulseResponse*

Get the last generated impulse response.

A new impulse response is generated when the method *corrupt_data* is called. You can use the *get_last_impulse_response* method to get the impulse response used to corrupt the last data.

Returns The impulse response of the channel that was used to corrupt the last data.

Return type *fading.TdlImpulseResponse*

property num_rx_antennas

Get the number of receive antennas.

Returns The number of receive antennas.

Return type *int*

property num_taps

Get the number of taps in the profile.

Returns The number of taps in the channel (not including any zero padding).

Return type *int*

property num_taps_with_padding

Get the number of taps in the profile including zero-padding when the profile is discretized.

If the profile is not discretized an exception is raised.

Returns The number of taps in the channel (including any zero padding).

Return type *int*

property num_tx_antennas

Get the number of transmit antennas.

Returns The number of transmit antennas.

Return type `int`

set_num_antennas (*num_rx_antennas: int, num_tx_antennas: int*) → `None`

Set the number of transmit and receive antennas for MIMO transmission.

Set both *num_rx_antennas* and *num_tx_antennas* to `None` for SISO transmission

Parameters

- **num_rx_antennas** (*int*) – The number of receive antennas.
- **num_tx_antennas** (*int*) – The number of transmit antennas.

set_pathloss (*pathloss_value: Optional[float] = None*) → `None`

Set the path loss (IN LINEAR SCALE).

The path loss will be accounted when calling the `corrupt_data` method.

If you want to disable the path loss, set *pathloss_value* to `None`.

Parameters **pathloss_value** (*float | None*) – The path loss (IN LINEAR SCALE) from the transmitter to the receiver. If you want to disable the path loss then set it to `None`.

Notes

Note that path loss is a power relation, which means that the channel coefficients will be multiplied by the square root of elements in *pathloss_value*.

property switched_direction

Get the value of *switched_direction*.

Returns True if direction is switched and False otherwise.

Return type `bool`

```
class pyphysim.channels.singleuser.SuMimoChannel (num_antennas: int, fading_generator: Optional[Union[pyphysim.channels.fading_generators.JakesSampler, pyphysim.channels.fading_generators.RayleighSampleGenerator]] = None, channel_profile: Optional[pyphysim.channels.fading.TdlChannelProfile] = None, tap_powers_dB: Optional[numpy.ndarray] = None, tap_delays: Optional[numpy.ndarray] = None, Ts: Optional[float] = None)
```

Bases: `pyphysim.channels.singleuser.SuChannel`

Single User channel corresponding to a Tapped Delay Line channel model, which corresponds to a multipath channel. You can use a single tap in order to get a flat fading channel.

You can create a new `SuMimoChannel` object either specifying the channel profile or specifying both the channel tap powers and delays. If only the `fading_generator` is specified then a single tap with unitary power and delay zero will be assumed, which corresponds to a flat fading channel model.

Parameters

- **num_antennas** (*int*) – Number of transmit and receive antennas.

- **fading_generator** (*FadingGenerator*) – The instance of a fading generator in the *fading_generators* module. It should be a subclass of *FadingSampleGenerator*. The fading generator will be used to generate the channel samples. If not provided then *RayleighSampleGenerator* will be used
- **channel_profile** (*fading.TdlChannelProfile*) – The channel profile, which specifies the tap powers and delays.
- **tap_powers_dB** (*np.ndarray*) – The powers of each tap (in dB). Dimension: $L \times 1$
Note: The power of each tap will be a negative number (in dB).
- **tap_delays** (*np.ndarray*) – The delay of each tap (in seconds). Dimension: $L \times 1$
- **Ts** (*float, optional*) – The sampling interval.

Module contents

Module with implementation of channel related classes.

pyphysim.comm package

Submodules

pyphysim.comm.blockdiagonalization module

Module implementing the block diagonalization algorithm.

There are two ways to use this module. You can either use the *BlockDiagonalizer* class, or you can use the *block_diagonalize()* and the *calc_receive_filter()* functions (which use the *BlockDiagonalizer* class in their implementation).

```
class pyphysim.comm.blockdiagonalization.BDWithExtIntBase (num_users: int, iPu: float, noise_var: float, pe: float)
Bases: pyphysim.comm.blockdiagonalization.BlockDiagonalizer
```

Class to perform the block diagonalization algorithm in a joint transmission scenario taking into account the external interference.

This is the base class for any block diagonalization class that takes into account the external interference.

Parameters

- **num_users** (*int*) – Number of users.
- **iPu** (*float*) – Power available for EACH user (in linear scale).
- **noise_var** (*float*) – Noise variance (power in linear scale).
- **pe** (*float*) – Power of the external interference source (in linear scale)

```
calc_whitening_matrices (mu_channel: pyphysim.channels.multiuser.MultiUserChannelMatrixExtInt)
→ List[numpy.ndarray]
```

Calculates the whitening receive filters for each user.

Note that to consider the noise variance it must be set in the provided *mu_channel* object.

Parameters mu_channel (*MultiUserChannelMatrixExtInt*) – A *MultiUserChannelMatrixExtInt* object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns `W_all_k` – The whitening matrices that each receiver should use to whiten the external interference. Each element in `W_all_k` is the whitening filter (with the conjugate transpose already applied) for a receiver.

Return type `list[np.ndarray]`

```
class pyphysim.comm.blockdiagonalization.BlockDiagonalizer(num_users: int, iPu:
                                                             float,      noise_var:
                                                             float)
```

Bases: `object`

Class to perform the block diagonalization algorithm in a joint transmission scenario.

In the block diagonalization algorithm either a single base station with more antennas transmits for multiple users at the same time or a group of base stations acts as a single transmitter to send data to the multiple users at the same time. In both cases the block diagonalization algorithm assures that each receiver does not see interference from the other receivers.

The water-filling algorithm is also applied to optimally distribute the power. However, in the case with multiple base stations, the power restriction in each base station must be respected. Therefore, after the power is optimally allocated at each base station all powers will be normalized to respect the power restriction of the base transmitting the highest energy. This is what is done in the `block_diagonalize()` method.

If the power should not be optimally allocated with the water-filling algorithm, use the `block_diagonalize_no_waterfilling()` method instead. The power restriction in each base station will still be respected, but the base station will equally divide its power among the available dimensions. Note that the result will be similar to `block_diagonalize()` in the high SNR regime.

Parameters

- **num_users** (*int*) – Number of users.
- **iPu** (*float*) – Power available for EACH user.
- **noise_var** (*float*) – Noise variance (power in linear scale).

Examples

Consider the case where we have 3 base station (BSs) jointly transmitting to 3 users, where each base station has a power of 1.5, the number of antennas (at each BS and at each receiver) is 2, and the noise variance is 1e-4. The channel can be block diagonalized for this scenario with

```
>>> bs_power = 1.5
>>> noise_var = 1e-4
>>> num_users = 2
>>> Ntx = 2 # Number of transmit antennas (per BS)
>>> Nrx = 2 # Number of receive antennas (per user)
>>> # Create the BlockDiagonalizer object
>>> bd = BlockDiagonalizer(num_users, bs_power, noise_var)
>>> channel = np.array([[ -0.9834-0.0123j,  0.6503-0.3189j,      0.5484+1.7049j, -
↪ 1.0891-0.1025j], [ -0.5911-0.3055j, -0.6205+0.3375j,      -0.7995+0.3723j,  0.
↪ 7412-1.2537j], [ -0.2732+0.475j , -0.4191+0.4019j,      0.1047-0.5592j,  0.7548-1.
↪ 0214j], [ 0.5377-0.208j , -0.1480-1.0527j,      -0.6373+0.4081j, -0.5854-0.
↪ 8135j]])
>>> (newH, Ms) = bd.block_diagonalize(channel)
```

We can see that the equivalent channel (after applying the `Ms` modulation matrix) is really block diagonalized.

```
>>> print(np.round(newH + 1e-10 + 1e-10j, 4))
[[ 0.0916+0.0135j -1.7449-0.4328j  0.      +0.j      0.      +0.j      ]
 [-0.0114-0.146j   0.0213-1.1366j  0.      +0.j      0.      +0.j      ]
 [ 0.      +0.j      0.      +0.j      0.0868+0.1565j -0.3673+0.2289j]
 [ 0.      +0.j      0.      +0.j      -0.0396+0.0407j  1.024  +0.8997j]]
```

Notice how the power restriction of each BS is respected (although only one BS will transmit with its maximum power).

```
>>> print(np.round(np.linalg.norm(Ms[:,0:Ntx])**2, 4))
1.4997
>>> print(np.round(np.linalg.norm(Ms[:,Ntx:])**2, 4))
1.5
```

Notes

The block diagonalization algorithm is described in [Spencer2004], where different power allocations are illustrated. The *BlockDiagonalizer* class implement two power allocation methods, a global power allocation, and a ‘per transmitter’ power allocation.

_calc_BD_matrix_no_power_scaling (*mtChannel*: *numpy.ndarray*) → Tuple[*numpy.ndarray*, *numpy.ndarray*]

Calculates the modulation matrix “M” that block diagonalizes the channel *mtChannel*, but without any kind of power scaling.

The “modulation matrix” is a matrix that changes the channel to a block diagonal structure and it is the first part in the Block Diagonalization algorithm. The returned modulation matrix is equivalent to Equation (12) of [Spencer2004] but without the power scaling matrix Λ . Therefore, for the complete BD algorithm it is still necessary to perform this power scaling in the output of `_calc_BD_matrix_no_power_scaling`.

Parameters *mtChannel* (*np.ndarray*) – Channel from the transmitter to all users.

Returns (*Ms_bad*, *Sigma*) – The modulation matrix “*Ms_bad*” is a precoder that block diagonalizes the channel. The singular values of the equivalent channel when the modulation matrix is applied correspond to *Sigma*. Therefore, *Sigma* can be used latter in the power allocation process.

Return type (*np.ndarray*, *np.ndarray*)

Notes

The reason why the Block Diagonalization algorithm was broken down into the code here and the power scaling code is because the power scaling may changing depending on the scenario. For instance, if the transmitter corresponds to a single base station the the power may be distributed into all the dimensions of the Modulation matrix. On the other hand, if the transmitter corresponds to multiple base stations jointly transmitting to multiple users then the power of each base station must be distributed only into the dimensions corresponding to that base station.

_get_sub_channel (*mt_channel*: *numpy.ndarray*, *desired_users*: Union[*int*, Iterable[*int*]]) → *numpy.ndarray*

Get a subchannel according to the *desired_users* vector.

Parameters

- **mt_channel** (*np.ndarray*) – Channel of all users (2D numpy array).

- **desired_users** (*list[int]*) – An iterable with the indexes of the desired users or an integer.

Returns **mtSubmatrix** – Submatrix of the desired users (2D numpy array)

Return type np.ndarray

Notes

As an example, let's consider the case with a channel for 3 receivers, each with 2 receive antennas, where the transmitter has 6 transmit antennas.

```
>>> BD = BlockDiagonalizer(3, 0, 0)
>>> channel = np.vstack([np.ones([2, 6]), 2 * np.ones([2, 6]),
    ↪          3 * np.ones([2, 6])])
>>> BD._get_sub_channel(channel, [0,2])
array([[1., 1., 1., 1., 1., 1.],
       [1., 1., 1., 1., 1., 1.],
       [3., 3., 3., 3., 3., 3.],
       [3., 3., 3., 3., 3., 3.]])
>>> BD._get_sub_channel(channel, 0)
array([[1., 1., 1., 1., 1., 1.],
       [1., 1., 1., 1., 1., 1.]])
```

_get_tilde_channel (*mtChannel: numpy.ndarray, user: int*) → *numpy.ndarray*

Return the combined channel of all users except *user*.

Let k be the index for *user*. If the channel from all transmitters to receiver k is mtH_k , then this method returns $\tilde{\text{mtH}}_k = [\text{mtH}_1^T, \dots, \text{mtH}_{k-1}^T, \text{mtH}_{k+1}^T, \dots, \text{mtH}_K^T]^T$.

Parameters

- **mtChannel** (*np.ndarray*) – Channel of all users (2D numpy array).
- **user** (*int*) – Index of the user.

Returns The combined channel of all users except *user*.

Return type np.ndarray

_perform_global_waterfilling_power_scaling (*Ms_bad: numpy.ndarray, Sigma: numpy.ndarray*) → *numpy.ndarray*

Perform the power scaling based on the water-filling algorithm for all the parallel channel gains in *Sigma*.

This power scaling method corresponds to maximizing the sum rate when the transmitter is a single base station transmitting to all users. Note that this approach may result in one or two “strong users” taking a dominant share of the available power.

Parameters

- **Ms_bad** (*np.ndarray*) – The previously calculated modulation matrix (without any power scaling). This should be a 2D numpy array.
- **Sigma** (*np.ndarray*) – The singular values of the effective channel when *Ms_bad* is applied. This should be a 1D numpy array of positive floats.

Returns **Ms_good** – The modulation matrix (2D numpy array) with the global power scaling applied.

Return type np.ndarray

`_perform_normalized_waterfilling_power_scaling` (*Ms_bad*: `numpy.ndarray`, *Sigma*: `numpy.ndarray`) → `numpy.ndarray`

Perform the power scaling based on the water-filling algorithm for all the parallel channel gains in *Sigma*, but normalize the result by the power of the base station transmitting with the highest power.

When we have a joint transmission where multiple base stations act as a single base station, then performing the water-filling on all the channels for the total available power may result in some base station transmitting with a higher power than it actually can. Therefore, we normalize the power of the strongest BS so that the power restriction at each BS is satisfied. This is sub-optimal since the other BSs will use less power than available, but it is simple and it works.

Parameters

- **Ms_bad** (`np.ndarray`) – The previously calculated modulation matrix (without any power scaling)
- **Sigma** (`np.ndarray`) – The singular values of the effective channel when *Ms_bad* is applied. This should be a 1D numpy array with positive values.

Returns **Ms_good** – The modulation matrix with the normalized power scaling applied. This is a 2D numpy array.

Return type `np.ndarray`

`block_diagonalize` (*mtChannel*: `numpy.ndarray`) → `Tuple[numpy.ndarray, numpy.ndarray]`

Perform the block diagonalization.

mtChannel is a matrix with the channel from the transmitter to all users, where each *iNUsers* rows correspond to one user.

For an example, see the documentation of the `BlockDiagonalizer` class.

Parameters **mtChannel** (`np.ndarray`) – Channel from (all) the transmitter(s) to all users. This should be a 2D numpy array.

Returns **newH** is a 2D numpy array corresponding to the Block diagonalized channel, while **Ms_good** is a 2D numpy array corresponding to the precoder matrix used to block diagonalize the channel.

Return type `np.ndarray, np.ndarray`

See also:

`block_diagonalize_no_waterfilling()`

`block_diagonalize_no_waterfilling` (*mtChannel*: `numpy.ndarray`) → `Tuple[numpy.ndarray, numpy.ndarray]`

Performs the block diagonalization, but without applying the water-filling algorithm.

The power of each base station is equally divided such that the square of the Frobenius norm of the columns of *Ms_good* corresponding to that base station is equal to its power.

Parameters **mtChannel** (`np.ndarray`) – Channel from (all) the transmitter(s) to all users. This should be a 2D numpy array.

Returns (**newH, Ms_good**) – **newH** is a 2D numpy array corresponding to the Block diagonalized channel, while **Ms_good** is a 2D numpy array corresponding to the precoder matrix used to block diagonalize the channel.

Return type (`np.ndarray, np.ndarray`)

See also:

`block_diagonalize()`

static `calc_receive_filter` (*newH*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the Zero-Forcing receive filter.

Parameters *newH* (*np.ndarray*) – The block diagonalized channel (2D numpy array).

Returns *W_bd* – The zero-forcing matrix (2D numpy array) to separate each stream of each user.

Return type *np.ndarray*

class `pyphysim.comm.blockdiagonalization.EnhancedBD` (*num_users*: *int*, *iPu*: *float*,
noise_var: *float*, *pe*: *float*)

Bases: `pyphysim.comm.blockdiagonalization.BDWithExtIntBase`

Class to perform the block diagonalization algorithm in a joint transmission scenario taking into account the external interference.

The EnhancedBD class performs the block diagonalization characteristic to the joint transmission scenario where multiple base stations act as a single transmitter to send data to the users. However, in addition to what the BlockDiagonalizer class does the EnhancedBD class can also take external interference into account.

One way to reduce or eliminate the external interference is to sacrifice streams in directions strongly occupied by the external interference.

Parameters

- **num_users** (*int*) – Number of users.
- **iPu** (*float*) – Power available for EACH user (in linear scale).
- **noise_var** (*float*) – Noise variance (power in linear scale).
- **pe** (*float*) – Power of the external interference source (in linear scale)

Notes

See the `BlockDiagonalizer` class for details about the block diagonalization process.

static `_calc_linear_SINRs` (*Heq_k_red*: *numpy.ndarray*, *Wk*: *numpy.ndarray*, *Re_k*:
numpy.ndarray) → *numpy.ndarray*

Calculates the effective SINRs of each parallel channel.

Parameters

- **Heq_k_red** (*np.ndarray*) – Equivalent channel matrix of user *k* including the block diagonalization and any stream reduction applied (2D numpy array).
- **Wk** (*np.ndarray*) – Receive filter for user *k* (2D numpy array).
- **Re_k** (*np.ndarray*) – A numpy array where each element is the covariance matrix of the external interference PLUS noise seen by a user (1D numpy array of 2D numpy arrays.).

Returns *sinrs* – SINR (in linear scale) of all the parallel channels of all users.

Return type *np.ndarray*

_perform_BD_no_waterfilling_decide_number_streams (*mu_channel*: *py-*
physim.channels.multiusers.MultiUserChannelMatrixE
→ *Tuple*[*numpy.ndarray*,
numpy.ndarray,
numpy.ndarray])

Function called inside `perform_BD_no_waterfilling` when the stream reduction is performed and the number of sacrificed streams depend on the metric used (the function set as `self._metric_func`).

Parameters `mu_channel` (`MultiUserChannelMatrixExtInt`) – A `MultiUserChannelMatrixExtInt` object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns

- **MsPk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the precoder for a user (1D numpy array of 2D numpy arrays).
- **Wk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the receive filter for a user (1D numpy array of 2D numpy arrays).
- **Ns_all_users** (`np.ndarray`) – Number of streams of each user (1D numpy array of ints).

`_perform_BD_no_waterfilling_fixed_or_naive_reduction` (`mu_channel`: `pyphysim.channels.multiuser.MultiUserChannelMatrixExtInt`)
→ `Tuple[numpy.ndarray, numpy.ndarray, numpy.ndarray]`

Function called inside `perform_BD_no_waterfilling` when the naive or the fixed stream reduction should be performed.

For the naive or the fixed stream reduction cases the number of transmitted streams is always equal to `self._metric_func_extra_args['num_streams']`. That is, the number of sacrificed streams is equal to the number of transmit antennas minus `num_streams`.

The only difference between the naive and the fixed cases is that in the fixed case the reduction matrix `P` is chosen so that it gets as orthogonal to the external interference as possible, while the naive case simply chooses `P` as a submatrix of the diagonal matrix.

Parameters `mu_channel` (`MultiUserChannelMatrixExtInt`) – A `MultiUserChannelMatrixExtInt` object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns

- **MsPk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the precoder for a user (1D numpy array of 2D numpy arrays).
- **Wk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the receive filter for a user (1D numpy array of 2D numpy arrays).
- **Ns_all_users** (`np.ndarray`) – Number of streams of each user (1D numpy array of ints).

`_perform_BD_no_waterfilling_no_stream_reduction` (`mu_channel`: `pyphysim.channels.multiuser.MultiUserChannelMatrixExtInt`)
→ `Tuple[numpy.ndarray, numpy.ndarray, numpy.ndarray]`

Function called inside `perform_BD_no_waterfilling` when no stream reduction should be performed.

Parameters `mu_channel` (`MultiUserChannelMatrixExtInt`) – A `MultiUserChannelMatrixExtInt` object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns

- **MsPk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the precoder for a user (1D numpy array of 2D numpy arrays).
- **Wk_all_users** (`np.ndarray`) – A 1D numpy array where each element corresponds to the receive filter for a user (1D numpy array of 2D numpy arrays).
- **Ns_all_users** (`np.ndarray`) – Number of streams of each user (1D numpy array of ints).

block_diagonalize_no_waterfilling (*mu_channel*: `pyphysim.channels.multiuser.MultiUserChannelMatrixExtInt`)
 → `Tuple[numpy.ndarray, numpy.ndarray, numpy.ndarray]`

Perform the block diagonalization of *mu_channel* taking the external interference into account.

This is the main method calculating the BD algorithm. Two important parameters used here are the noise variance (an attribute of the *mu_channel* object) and the external interference power (the *pe* attribute) attributes.

Parameters *mu_channel* (*MultiUserChannelMatrixExtInt* object.) – A *MultiUserChannelMatrixExtInt* object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns

- **MsPk_all_users** (*np.ndarray*) – A 1D numpy array where each element corresponds to the precoder for a user (1D numpy array of 2D numpy arrays).
- **Wk_all_users** (*np.ndarray*) – A 1D numpy array where each element corresponds to the receive filter for a user (1D numpy array of 2D numpy arrays).
- **Ns_all_users** (*np.ndarray*) – Number of streams of each user (1D numpy array of ints).

static calc_receive_filter_user_k (*Heq_k_P*: `numpy.ndarray`, *P*: `Optional[numpy.ndarray] = None`) → `numpy.ndarray`

Calculates the Zero-Forcing receive filter of a single user *k* with or without the stream reduction.

Parameters

- **Heq_k_P** (*np.ndarray*) – The equivalent channel of user *k* after the block diagonalization process and any stream reduction (2D numpy array).
- **P** (*np.ndarray*, *optional*) – *P* has the most significant singular vectors of the external interference plus noise covariance matrix for each receiver.

Returns *W* – The receive filter of user *k* (2D numpy array).

Return type `np.ndarray`

Notes

If *P* is not *None* then the number of transmit streams will be equal to the number of columns in *P*. Also, the receive filter *W* includes a projection into the subspace spanned by the columns of *P*. Since *P* was calculated to be in the directions with weaker (or no) external interference then the receive filter *W* will mitigate the external interference.

property metric_name

Get name of the method used to decide how many streams to sacrifice.

Returns The metric name.

Return type `str`

set_ext_int_handling_metric (*metric*: `Optional[str]`, *metric_func_extra_args_dict*: `Optional[Dict[str, Any]] = None`) → `None`

Set the metric used to decide how many streams to sacrifice for external interference handling.

The modification to the standard Block Diagonalization algorithm performed in this class consists in avoid transmit data in the subspace strongly occupied by the external interference source.

This sacrificing (not transmitting) of streams may or may not be worth it and different metrics can be used to decide this.

The valid values for the *metric* argument are ‘None’ (python None object), “fixed”, “naive”, “capacity” and “effective_throughput”. Each of these values will impact on how the number of transmit streams is chosen and which subspace is actually used for the desired signal.

For the “fixed” and “naive” metrics, the number of transmit streams is determined by the value of the ‘num_streams’ key in the *metric_func_extra_args_dict*. The difference between them is how the subspace where the useful data is determined (for the given number of sacrificed streams).

For the “naive” metric, the stream reduction is performed by multiplying the usual block diagonalizing matrix *M* by a subset of the identity matrix. For the “fixed” metric the subspace containing the lowest remaining external interference energy is chosen by multiplying the block diagonalizing matrix *M* by the singular vectors of the external interference covariance matrix corresponding to the lowest singular values. The same procedure is used for the other metrics.

Differently from the “naive” and “fixed” metrics, the “capacity” and “effective_throughput” metrics try to determine this best number of sacrificed streams.

- If *metric* is None, then all streams will be used. That is, no streams will be sacrificed and the external interference won’t be mitigated.
- If *metric* is “None” or “naive” then the specified number of streams will be used.
- If *metric* is ‘capacity’, then the metric used to decide how many streams to sacrifice will be the sum capacity. The function *calc_shannon_sum_capacity()* will be used to calculate the sum capacity metric, and since it only uses the SINR values, no extra arguments are required in the *metric_func_extra_args_dict* dictionary.
- If *metric* is ‘effective_throughput’ then the metric used to decide how many streams to sacrifice will be the effective throughput that can be obtained. The function *_calc_effective_throughput* will be used to calculate the effective throughput. Since it requires the a modulator and a packet length you should set the *metric_func_extra_args_dict* so that it has the keys ‘modulator’ and ‘packet_length’ with the correct values (a modulator object and an integer, respectively)

Parameters

- **metric** (*str* | *None*) – The metric name. Must be one of the available metrics: {None, ‘capacity’, ‘effective_throughput’}.
- **metric_func_extra_args_dict** (*dict*) – A dictionary containing the extra arguments that must be passed to the metric function. For the “naive” and “fixed” metrics, this dictionary must contain the “num_streams” keyword with the desired number of transmit streams. For the “effective_throughput” metric this dictionary must contain the “modulator” and “packet_length” keywords with a modulator object and an integer, respectively. For the other metrics *metric_func_extra_args_dict* will be ignored.

Raises *AttributeError* – If the metric is not one of the available metrics or if the *metric_func_extra_args_dict* does not contain the required keywords.

```
class pyphysim.comm.blockdiagonalization.WhiteningBD(num_users: int, iPu: float,  
                                                    noise_var: float, pe: float)
```

Bases: *pyphysim.comm.blockdiagonalization.BDWithExtIntBase*

Class to perform the block diagonalization algorithm in a joint transmission scenario taking into account the external interference.

Parameters

- **num_users** (*int*) – Number of users.
- **iPu** (*float*) – Power available for EACH user (in linear scale).
- **noise_var** (*float*) – Noise variance (power in linear scale).

- **pe** (*float*) – Power of the external interference source (in linear scale)

static _calc_receive_filter_with_whitening (*newH: numpy.ndarray, whitening_filter: numpy.ndarray, Nr: numpy.ndarray, Nt: numpy.ndarray*) → *numpy.ndarray*

Calculates the Zero-Forcing receive filter of all users.

Parameters

- **newH** (*np.ndarray*) – The block diagonalized channel (with the whitening applied). This should be a 2D numpy array.
- **whitening_filter** (*np.ndarray*) – The whitening filter of all users. This is a block diagonal matrix where each “block” is the whitening filter of a user.
- **Nr** (*np.ndarray*) – The number of receive antennas of each user.
- **Nt** (*np.ndarray*) – The number of transmit antennas of each user.

Returns **Wk_all_users** – A 1D numpy array where each element corresponds to the receive filter for a user. This is a 1D numpy array of 2D numpy arrays.

Return type *np.ndarray*

block_diagonalize_no_waterfilling (*mu_channel: pyphysim.channels.multisuser.MultiUserChannelMatrixExtInt*) → *Tuple[numpy.ndarray, numpy.ndarray, numpy.ndarray]*

Perform the block diagonalization of *mu_channel* taking the external interference into account.

Parameters **mu_channel** (*MultiUserChannelMatrixExtInt*) – A *MultiUserChannelMatrixExtInt* object, which has the channel from all the transmitters to all the receivers, as well as the external interference.

Returns

- **Ms_all_users** (*np.ndarray*) – A 1D numpy array where each element corresponds to the precoder for a user (1D numpy array of 2D numpy arrays).
- **Wk_all_users** (*np.ndarray*) – A 1D numpy array where each element corresponds to the receive filter for a user (1D numpy array of 2D numpy arrays).
- **Ns_all_users** (*np.ndarray*) – Number of streams of each user (1D numpy array of ints).

pyphysim.comm.blockdiagonalization.block_diagonalize (*mtChannel: numpy.ndarray, num_users: int, iPu: float, noise_var: float*) → *Tuple[numpy.ndarray, numpy.ndarray]*

Performs the block diagonalization of *mtChannel*.

Parameters

- **mtChannel** (*np.ndarray*) – Global channel matrix (a 2D numpy array).
- **num_users** (*int*) – Number of users
- **iPu** (*float*) – Power available for each user
- **noise_var** (*float*) – Noise variance

Returns (**newH, Ms_good**) – *newH* is a 2D numpy array corresponding to the Block diagonalized channel, while *Ms_good* is a 2D numpy array corresponding to the precoder matrix used to block diagonalize the channel.

Return type (*np.ndarray, np.ndarray*)

Notes

The block diagonalization algorithm is described in [Spencer2004], where different power allocations are illustrated. The *BlockDiagonalizer* class implement two power allocation methods, a global power allocation, and a ‘per transmitter’ power allocation.

`pyphysim.comm.blockdiagonalization.calc_receive_filter` (*newH*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the Zero-Forcing receive filter.

Parameters *newH* (*np.ndarray*) – The block diagonalized channel.

Returns The zero-forcing matrix to separate each stream of each user. Note that *W_bd_H* is directly applied to the received signals (no need to calculate the conjugate transpose).

Return type *np.ndarray*

pyphysim.comm.waterfilling module

Implements a waterfilling method.

The doWF method performs the waterfilling algorithm.

`pyphysim.comm.waterfilling.doWF` (*vtChannels*: *numpy.ndarray*, *dPt*: *float*, *noiseVar*: *float* = 1.0, *Es*: *float* = 1.0) → *Tuple*[*numpy.ndarray*, *float*]

Performs the Waterfilling algorithm and returns the optimum power and water level.

Parameters

- **vtChannels** (*np.ndarray*) – Numpy array with the channel POWER gains (power of the parallel AWGN channels).
- **dPt** (*float*) – Total available power.
- **noiseVar** (*float*) – Noise variance (power in linear scale).
- **Es** (*float*) – Symbol energy (in linear scale).

Returns (*vtOptP*, *mu*) – A tuple with *vtOptP* and *mu*, where *vtOptP* are the optimum powers, while *mu* is the water level.

Return type (*np.ndarray*, *float*)

Module contents

pyphysim.extra package

Subpackages

pyphysim.extra.MATLAB package

Submodules

pyphysim.extra.MATLAB.python2MATLAB module

Module with functions to easily moving data from python to MATLAB.

`pyphysim.extra.MATLAB.python2MATLAB.to_mat_str(x, format_string='+.12e')`

Convert the ndarray 'x' to a string corresponding to the MATLAB representation of x.

The `to_mat_str` function formats numpy arrays of arbitrary dimension in a way which can easily copied and pasted into an interactive MATLAB session

Parameters

- **x** (*numpy array*) – The numpy array to be represented as a MATLAB type.
- **format_string** (*str, optional*) – The format_string string to convert each element in x.

Returns `converted_string` – A string that represents the converted numpy array. You can copy this string and past it into a MATLAB session.

Return type `str`

Examples

```
>>> a=np.arange(1,10)
>>> a.shape=(3,3)
>>> # Print as a numpy matrix
>>> print(a)
[[1 2 3]
 [4 5 6]
 [7 8 9]]
>>> # Call to_mat_str(a) to print the string representation of the
>>> # converted matrix
>>> print(to_mat_str(a))
[+1.000000000000e+00, +2.000000000000e+00, +3.000000000000e+00; +4.
↪ 000000000000e+00, +5.000000000000e+00, +6.000000000000e+00; +7.000000000000e+00,
↪ +8.000000000000e+00, +9.000000000000e+00]
```

Module contents

Package with MATLAB related functions.

Examples: conversions for the print output from python to MATLAB and vice-verse. That way you can print a numpy array, copy the output and past in MATLAB for further analysis.

Submodules

pyphysim.extra.pgplotshelper module

This module contains useful functions to create pgfplots code (latex code using the pgfplots package) from python data.

One example of tex code for a plot using pgfplots is show below

```
\begin{tikzpicture}
  \begin{axis}[axis options]
    \addplot [plot options]
      plot [options]
        coordinates {
          (0, 0)
          (1, 1)
          (2, 4)
          (3, 9)};
    \addlegendentry{Legend of the last line};
  \end{axis}
\end{tikzpicture}
```

```
pyphysim.extra.pgplotshelper.generate_pgplots_plotline(x, y, errors=None,
                                                         options=None, legend=
                                                         end=None)
```

This function generates the code corresponding to the “addplot” command in a pgfplots plot for the coordinates given in x and y .

If the parameter *errors* is also provided then error bars will be added in the y direction, while options to the addplot command can be passed as a string in the *options* argument.

Parameters

- **x** (*np.ndarray* | *list[float]* | *list[int]*) – The data for the ‘x’ axis in the plot.
- **y** (*np.ndarray* | *list[float]* | *list[int]*) – The data for the ‘y’ axis in the plot
- **errors** (*np.ndarray* | *list[float]* | *list[int]*, *optional*) – The error for plotting the errorbars.
- **options** (*str*) – pgfplot options for the plot line. Ex: “color=red, solid, mark=square, mark options={solid}”
- **legend** (*str*) – The legend for the plot line.

Module contents

Package containing extra functionality.

pyphysim.ia package

Submodules

pyphysim.ia.algorithms module

Module with implementation of Interference Alignment (IA) algorithms.

Note that all IA algorithms require the channel object and any change to the channel object must be performed before calling the *solve* method of the IA algorithm object. This includes generating the channel and setting the noise variance.

class `pyphysim.ia.algorithms.AlternatingMinIASolver` (*multiUserChannel*: `pyphysim.channels.multiuser.MultiUserChannelMatrix`)

Bases: `pyphysim.ia.algorithms.IterativeIASolverBaseClass`

Implements the “Interference Alignment via Alternating Minimization” algorithm from the paper with the same name [PetersHeathAltMin2009].

This algorithm is applicable to a “K-user” scenario and it is very flexible in the sense that you can change the number of transmit antennas, receive antennas and streams per user, as well as the number of users involved in the IA process. However, note that alignment is only feasible for some cases configurations.

An example of a common scenario is a scenario with 3 pairs of transmitter/receiver with 2 antennas in each node and 1 stream transmitted per node.

You can determine the scenario of an AlternatingMinIASolver object by inferring the variables K, Nt, Nr and Ns.

Parameters `multiUserChannel` (`muchannels.MultiUserChannelMatrix`) – The multiuser channel.

Notes

`__before_initialize_W_func()` → `None`

Method run in any of the initialize methods after the precoder is initialized but before the receive filter is initialized.

`__solve_finalize()` → `None`

Perform any post processing after the solution has been found.

`__step()` → `None`

Performs one iteration of the algorithm.

The step method is usually all you need to call to perform an iteration of the Alternating Minimization algorithm. It will update C, then update F and finally update W.

See also:

`__updateC()`, `__updateF()`, `__updateW()`

`__updateC()` → `None`

Update the value of Ck for all K users.

C_k contains the orthogonal basis of the interference subspace of user k . It corresponds to the $N_k - S_k$ dominant eigenvectors of

$$\sum_{l \neq k} H_{k,l} H_{k,l}^H.$$

Notes

This method is called in the `_step()` method.

See also:

`_step()`

`_updateF()` → `None`

Update the value of the precoder of all K users.

F_l , the precoder of the l -th user, tries avoid as much as possible to send energy into the desired signal subspace of the other users. F_l contains the S_l least dominant eigenvectors of $\sum_{k \neq l} H_{k,l}^H (I - C_k C_k^H) H_{k,l}$.

Notes

This method is called in the `_step()` method.

See also:

`_step()`

`_updateW()` → `None`

Update the zero-forcing filters.

The zero-forcing filter is calculated in the paper “MIMO Interference Alignment Over Correlated Channels with Imperfect CSI”.

Notes

This method is called in the `_step()` method.

See also:

`_step()`

`get_cost()` → `float`

Get the Cost of the algorithm for the current iteration of the precoder.

Returns `cost` – The Cost of the algorithm for the current iteration of the precoder. This is a real non-negative number.

Return type `float`

property initialize_with

Get method for the initialize_with property.

class `pyphysim.ia.algorithms.BruteForceStreamIASolver` (*iasolver_obj*: `pyphysim.ia.algorithms.IterativeIASolverBaseClass`)

Bases: `object`

Implements the Brute Force Stream Interference Alignment algorithm variation.

This is not a new IA algorithm, but rather a variation of existing IA algorithms. The idea is to use another IA algorithm to find the IA solution for each possible stream configuration (number of streams for each user) and keep the best one.

Note: IA algorithms can provide different performance for the same number of streams but with different initializations. To reduce this variability we set the initialization method to 'svd' (see 'initialize_with' property in the IterativeIASolverBaseClass class) so that the initialization is always the same.

Parameters `iasolver_obj` ($T \leq \text{IASolverBaseClass}$) – Must be an object of a derived class of IterativeIASolverBaseClass.

`clear()` → `None`

Clear the BruteForceStreamIASolver object.

property `every_sum_capacity`

Get method for the every_sum_capacity property.

Returns Tuple containing the sum capacity for each stream combination in `self.stream_combinations`.

Return type `list`

property `runned_iterations`

Get method for the runned_iterations property.

Returns The number of runned iterations.

Return type `int`

solve (`Ns: IntOrIntSequence`, `P: Optional[FloatOrFloatSequence] = None`) → `int`

Find the IA solution.

This method updates the 'F' and 'W' member variables.

Parameters

- **Ns** (`int` | `np.ndarray`) – MAXIMUM number of streams of each user. All possible values from 1 to Ns (or Ns[k], if Ns is an array) will be tried.
- **P** (`np.ndarray` | `List[float]` | `float`, *optional*) – Power of each user. If not provided, a value of 1 will be used for each user.

Returns Number of iterations the iterative interference alignment algorithm run.

Return type `int`

property `stream_combinations`

Get method for the stream_combinations property.

Returns Tuple containing every possible stream combination.

Return type `tuple`

class `pyphysim.ia.algorithms.ClosedFormIASolver` (`multiUserChannel: pyphysim.channels.multiuser.MultiUserChannelMatrix`, `use_best_init: bool = True`)

Bases: `pyphysim.ia.iabase.IASolverBaseClass`

Implements the closed form Interference Alignment algorithm as described in the paper “Interference Alignment and Degrees of Freedom of the K User Interference Channel [CadambeDoF2008]”.

Parameters

- **multiUserChannel** (`muchannels.MultiUserChannelMatrix`) – The multiuser channel.
- **use_best_init** (`bool`) – If true, all possible initializations (subsets of the eigenvectors of the 'E' matrix) for the first precoder will be tested and the best solution will be used. If false, the first initialization will be used.

Notes

_calc_E() → `numpy.ndarray`

Calculates the “E” matrix, given by

$$= \begin{matrix} -1 & -1 & -1 \\ 31 & 32 & 13 \\ 21 & 23 & 21 \end{matrix}.$$

Returns The “E” matrix.

Return type `np.ndarray`

_calc_all_F_initializations (*Ns: int*) → `List[numpy.ndarray]`

Calculates all possible initializations for the first precoder (`self._F[0]`).

The precoder `self._F[0]` is initialized with a subset of the eigenvectors of the matrix ‘E’. Therefore, this method returns all possible subsets of the eigenvectors of the matrix ‘E’.

Parameters **Ns** (*int*) – Number of streams of the first user.

Returns **all_initializations** – All possible subsets (with size *Ns*) of the eigenvectors of the matrix E

Return type `list[np.ndarray]`

_updateF (*F0: Optional[numpy.ndarray] = None*) → `None`

Find the precoders.

Parameters **F0** (*np.ndarray*) – The first precoder. If not provided, the matrix ‘E’ will be calculated (with the `_calc_E` method) and the the first *Ns* eigenvectors will be used as *F0*.

_updateW () → `None`

Find the receive filters

solve (*Ns: IntOrIntSequence, P: Optional[FloatOrFloatSequence] = None*) → `None`

Find the IA solution.

This method updates the ‘F’ and ‘W’ member variables.

Parameters

- **Ns** (*int | np.ndarray*) – Number of streams of each user.
- **P** (*np.ndarray | List[float] | float, optional*) – Power of each user. If not provided, a value of 1 will be used for each user.

class `pyphysim.ia.algorithms.GreedStreamIASolver` (*iasolver_obj: Type[pyphysim.ia.iabase.IASolverBaseClass]*)

Bases: `object`

Implements the Greed Stream Interference Alignment algorithm variation.

This is not a new IA algorithm, but rather a variation of existing IA algorithms. The idea is to use another IA algorithm to find the IA solution for the desired maximum number of streams. After the solution is found, we remove the worst stream and use the same algorithm again to find a new solution. If the solution after the stream reduction provided a larger sum capacity we remove the worst stream again and keep going until each user has only one stream or the sum capacity after stream reduction is lower. The final solution will be for the number of streams that yielded the largest sum capacity.

Parameters **iasolver_obj** (*T <= IASolverBaseClass*) – Must be an object of a derived class of `IterativeIASolverBaseClass`.

_find_index_stream_with_worst_sinr () → `Tuple[int, int]`

Considering the current solution (precoders and receive filters) in `self._iasolver`, find the index of the user and stream corresponding to the worst SINR.

Returns

- **user_idx** (*int*) – The index of the user that has the stream with the worst SINR.
- **stream_idx** (*int*) – The index of the stream (for user *user_idx*) with the worst SINR.

property `runned_iterations`

Get method for the runned_iterations property.

Returns The number of runned iterations.

Return type `int`

solve (*Ns: IntOrIntSequence, P: Optional[FloatOrFloatSequence] = None*) → `int`

Find the IA solution.

This method updates the ‘F’ and ‘W’ member variables.

Parameters

- **Ns** (*int* | *np.ndarray*) – Number of streams of each user.
- **P** (*np.ndarray* | *List[float]* | *float, optional*) – Power of each user.
If not provided, a value of 1 will be used for each user.

Returns Number of iterations the iterative interference alignment algorithm run.

Return type `int`

class `pyphysim.ia.algorithms.IterativeIASolverBaseClass` (*multiUserChannel: py-*
physim.channels.multiuser.MultiUserChannelMatrix)

Bases: `pyphysim.ia.iabase.IASolverBaseClass`

Base class for all Iterative IA algorithms.

All subclasses of `IterativeIASolverBaseClass` must implement at least the `_updateF` and `_updateW` methods.

Solving an iterative algorithm usually involves some initialization and then performing a “step” a given number of times until convergence. The initialization code is performed in the `_solve_init` method while the “step” corresponds to the `_step` method.

The initialization code is defined here as simply initializing the precoder with a random matrix and then calling the `_updateW` method (which must be implemented in a subclass) to update the receive filter. This is usually what you want but any subclass can redefine `_solve_init` if a different initialization is required.

The “step” part usually involves updating the precoder and then updating the receive filters. The definition of `_step` here calls two methods that **MUST** be defined in subclasses, the `_updateF` method and the `_updateW` method. If anything else is required in the “step” part then the `_step` method can be redefined in a subclass, but even in that case it should call the `_updateF` and `_updateW` methods instead of implementing everything in your redefined `_step` method.

Parameters **multiUserChannel** (*muchannels.MultiUserChannelMatrix*) – The multiuser channel.

_before_initialize_W_func () → `None`

Method run in any of the initialize methods after the precoder is initialized but before the receive filter is initialized.

_dont_initialize_F_and_only_and_find_W (*_: *Any*) → `None`

Initialize the IA Solution from a random matrix.

The implementation here simple initializes the precoder variable and then calculates the initial receive filter.

Note: The *dummy1* and *dummy2* arguments have no effect. They only exist to keep the signature of this method equal to the signature of other *initialize* methods.

`_initialize_F_and_W_from_alt_min` (*Ns: IntOrIntSequence, P: `numpy.ndarray`*) → `None`
Initialize the IA Solution from the Alternating Minimizations IA solver.

Parameters

- **`Ns`** (*int | `np.ndarray`*) – Number of streams of each user.
- **`P`** (*`np.ndarray`*) – Power of each user. If not provided, a value of 1 will be used for each user.

`_initialize_F_and_W_from_closed_form` (*Ns: IntOrIntSequence, P: `numpy.ndarray`*) → `None`
Initialize the IA Solution from the closed form IA solver.

Parameters

- **`Ns`** (*int | `np.ndarray`*) – Number of streams of each user.
- **`P`** (*`np.ndarray`*) – Power of each user. If not provided, a value of 1 will be used for each user.

`_initialize_F_randomly_and_find_W` (*Ns: `Sequence[int]`, P: `numpy.ndarray`*) → `None`
Initialize the IA Solution from a random matrix.

The implementation here simple initializes the precoder variable and then calculates the initial receive filter.

Parameters

- **`Ns`** (*int | `np.ndarray`*) – Number of streams of each user.
- **`P`** (*`np.ndarray`*) – Power of each user. If not provided, a value of 1 will be used for each user.

`_initialize_F_with_svd_and_find_W` (*Ns: IntOrIntSequence, P: `numpy.ndarray`*) → `None`
Initialize the IA Solution from the most significant singular vectors of each user's channel.

The implementation here simple initializes the precoder variable of each user as the most significant singular vector(s) of that user. After that, calculate the initial receive filters.

Parameters

- **`Ns`** (*int | `np.ndarray`*) – Number of streams of each user.
- **`P`** (*`np.ndarray`*) – Power of each user. If not provided, a value of 1 will be used for each user.

`classmethod _is_diff_significant` (*F_old: `numpy.ndarray`, F_new: `numpy.ndarray`, relative_factor: `float`*) → `bool`

Test if there was any significant change from *F_old* to *F_new*.

This method is used internally in the solve method of the `IterativeIASolverBaseClass` to detect when the precoder of a given iteration didn't change significantly from one iteration to another. This is used to stop the iterations of the algorithm and avoid unnecessary computations.

Parameters

- **`F_old`** (*`np.ndarray`*) – The precoder of all users (in a previous iteration). This is a 1D numpy array of numpy arrays.
- **`F_new`** (*`np.ndarray`*) – The precoder of all users (in the current iteration). This is a 1D numpy array of numpy arrays.
- **`relative_factor`** (*`float`*) – Relative change of the precoder in one iteration to the next one. If the relative change from one iteration to the next one is lower than this factor then the algorithm will stop the iterations before the `max_iterations` limit is reached.

Returns out – True if the difference is significant, False otherwise.

Return type `bool`

Notes

A difference is considered significant if it is larger then 1/1000 of the minimum value in the precoder.

`_solve_finalize()` → `None`

Perform any post processing after the solution has been found.

Some of the found precoders may be a singular matrix. In that case, we need to remove the dimensions with zero energy from both the found precoder and the receive filter.

`_solve_init(Ns: IntOrIntSequence, P: FloatOrFloatSequence)` → `None`

Code run in the *solve* method before the loop that run the `_step()` method.

The implementation here simple initializes the precoder variable and then calculates the initial receive filter.

Parameters

- **`Ns`** (`int` | `np.ndarray`) – Number of streams of each user.
- **`P`** (`float` | `np.ndarray`) – Power of each user. If not provided, a value of 1 will be used for each user.

`_step()` → `None`

Performs one iteration of the algorithm.

This method does not return anything, but instead updates the precoder and receive filter.

`abstract _updateF()` → `None`

Update the precoders.

Notes

This method should be implemented in the derived classes

See also:

`_step()`

`abstract _updateW()` → `None`

Update the receive filters.

Notes

This method should be implemented in the derived classes

See also:

`_step()`

`clear()` → `None`

Clear the IA Solver object.

All member attributes that are updated during the solve method, such as the precoder and receive filters, will be cleared. The other attributes that correspond to “configuration” such as the channel object won’t be changed

Notes

You should overwrite this method in subclasses that pass parameters to the `__init__` method, since here we call `__init__` without arguments which is probably not what you want.

`property initialize_with`

Get method for the `initialize_with` property.

randomizeF (*Ns*: `Union[int, List[int], Sequence[int]]`, *P*: `Optional[numpy.ndarray] = None`) → `None`

Generates a random precoder for each user.

Parameters

- **Ns** (`int | list[int] | np.ndarray`) – Number of streams of each user.
- **P** (`np.ndarray, optional`) – Power of each user. If not provided, a value of 1 will be used for each user.

`property runned_iterations`

Get method for the `runned_iterations` property.

solve (*Ns*: `IntOrIntSequence`, *P*: `Optional[FloatOrFloatSequence] = None`) → `int`

Find the IA solution by performing the `_step()` method several times.

The number of times the `_step()` method is run is controlled by the `max_iterations` member variable.

Before calling the `_step()` method for the first time the `_solve_init` method is called to perform any required initializations. Since iterative IA algorithms usually starts with a random precoder then the `_solve_init` implementation in `IterativeIASolverBaseClass` calls `randomizeF`.

Parameters

- **Ns** (`int | np.ndarray`) – Number of streams of each user.
- **P** (`np.ndarray | List[float] | float, optional`) – Power of each user. If not provided, a value of 1 will be used for each user.

Returns

- *Number of iterations that the iterative interference alignment*
- *algorithm run.*

Notes

You probably should not overwrite this method in sub-classes of the `IterativeIASolverBaseClass`. If you want to change the initialization of the algorithm overwrite the `_solve_init` method instead.

Subclasses must implement the `_updateF()` and `_updateW()` methods. If something else besides calling these two methods is required in the “step” part of the algorithm, then reimplement also the `_step()` method.

class `pyphysim.ia.algorithms.MMSEIASolver` (*multiUserChannel*: `py-`
`physim.channels.multiuser.MultiUserChannelMatrix`)
Bases: `pyphysim.ia.algorithms.IterativeIASolverBaseClass`

Implements the MMSE based Interference Alignment algorithm.

This algorithm is applicable to a “K-user” scenario and it is described in [Peters2011].

An example of a common scenario is a scenario with 3 pairs of transmitter/receiver with 2 antennas in each node and 1 stream transmitted per node.

You can determine the scenario of an `MMSEIASolver` object by inferring the variables `K`, `Nt`, `Nr` and `Ns`.

Parameters `multiUserChannel` (`muchannels.MultiUserChannelMatrix`) – The multiuser channel.

Notes

`_calc_Uk` (`k: int`) → `numpy.ndarray`

Calculates the receive filter of the k-th user.

Parameters `k` (`int`) – User index

Returns `Uk` – The receive filter of the user ‘k’.

Return type `np.ndarray`

`_calc_Vi` (`i: int, mu_i: Optional[float] = None`) → `numpy.ndarray`

Calculates the precoder of the i-th user.

Parameters

- `i` (`int`) – User index
- `mu_i` (`float, optional`) – The value of the Lagrange multiplier. If it is None (default), then the best value will be found and used to calculate the precoder.

Returns `Vi` – The calculate precoder of the i-th user.

Return type `np.ndarray`

static `_calc_Vi_for_a_given_mu` (`sum_term: numpy.ndarray, mu_i: float, H_herm_U: numpy.ndarray`) → `numpy.ndarray`

Calculates the value of Vi for the given parameters.

This method is called inside `_calc_Vi`.

Parameters

- `sum_term` (`np.ndarray`) – The summation term in the formula to calculate the precoder.
- `mu_i` (`float`) – The value of the lagrange multiplier
- `H_herm_U` (`np.ndarray`) – The value of $H_i i^H U_i$

Returns The Vi matrix for the given parameters.

Return type `np.ndarray`

static `_calc_Vi_for_a_given_mu2` (`inv_sum_term: numpy.ndarray, mu_i: float, H_herm_U: numpy.ndarray`) → `numpy.ndarray`

Calculates the value of Vi for the given parameters.

This method is called inside `_calc_Vi`.

Parameters

- `inv_sum_term` (`np.ndarray`) – The inverse of the summation term in the formula to calculate the precoder when mu_i is equal to zero.
- `mu_i` (`float`) – The value of the lagrange multiplier
- `H_herm_U` (`np.ndarray`) – The value of $H_i i^H U_i$

Returns The Vi matrix for the given parameters.

Return type `np.ndarray`

`_solve_init (Ns: IntOrIntSequence, P: numpy.ndarray) → None`

Code run in the `solve` method before the loop that run the `IterativeIASolverBaseClass._step()` method.

The implementation here simple initializes the precoder variable and then calculates the initial receive filter.

Parameters

- **Ns** (`int` | `np.ndarray`) – Number of streams of each user.
- **P** (`np.ndarray`) – Power of each user. If not provided, a value of 1 will be used for each user.

`_updateF () → None`

Updates the precoder of all users.

`_updateW () → None`

Updates the receive filter of all users.

class `pyphysim.ia.algorithms.MaxSinrIASolver` (`multiUserChannel: py-`
`physim.channels.multiuser.MultiUserChannelMatrix`)
Bases: `pyphysim.ia.algorithms.IterativeIASolverBaseClass`

Implements the “Interference Alignment via Max SINR” algorithm.

This algorithm is applicable to a “K-user” scenario and it is described in [Cadambe2008].

An example of a common scenario is a scenario with 3 pairs of transmitter/receiver with 2 antennas in each node and 1 stream transmitted per node.

You can determine the scenario of an `MaxSinrIASolver` object by inferring the variables K, Nt, Nr and Ns.

Parameters `multiUserChannel` (`muchannels.MultiUserChannelMatrix`) – The multiuser channel.

`_calc_Bkl_cov_matrix_all_l_rev (k: int) → numpy.ndarray`

Calculates the interference-plus-noise covariance matrix for all streams at “receiver” *k* for the reverse channel.

Parameters `k` (`int`) – Index of the desired user.

Returns `Bkl_rev` – Covariance matrix of all streams of user *k*. Each element of the returned 1D numpy array is a 2D numpy complex array corresponding to the covariance matrix of one stream of user *k*.

Return type `np.ndarray`

`_calc_Bkl_cov_matrix_first_part_rev (k: int) → numpy.ndarray`

Calculates the first part in the equation of the `Blk` covariance matrix of the reverse channel.

Parameters `k` (`int`) – Index of the desired user.

Returns `Bkl_first_part_rev` – First part in equation (28) of [Cadambe2008], but for the reverse channel.

Return type `np.ndarray`

See also:

`_calc_Bkl_cov_matrix_first_part_rev()`

`_calc_Bkl_cov_matrix_second_part_rev (k: int, l: int) → numpy.ndarray`

Calculates the second part in the equation of the `Blk` covariance matrix of the reverse channel..

The second part is given by

$$\frac{P^{[k]} [kk] [k] [k] \dagger [kk] \dagger}{d^{[k]} \star l \star l}$$

Parameters

- **k** (*int*) – Index of the desired user.
- **l** (*int*) – Index of the desired stream.

Returns **second_part** – Second part in equation (28) of [Cadambe2008].

Return type np.ndarray

classmethod **_calc_Uk** (*Hkk: numpy.ndarray, Vk: numpy.ndarray, Bkl_all_l: numpy.ndarray*) → *numpy.ndarray*

Similar to the `_calc_Ukl()` method, but while `_calc_Ukl()` calculates the receive filter (a vector) only for the *l*-th stream `_calc_Uk()` calculates a receive filter (a matrix) for all streams.

Parameters

- **Hkk** (*np.ndarray*) – Channel from transmitter K to receiver K.
- **Vk** (*np.ndarray*) – Precoder of user k.
- **Bkl_all_l** (*np.ndarray*) – Covariance matrix of all streams of user k. Each element of the returned 1D numpy array is a 2D numpy complex array corresponding to the covariance matrix of one stream of user k.

Returns **Uk** – The receive filter for all streams of user k.

Return type np.ndarray

_calc_Uk_all_k () → *numpy.ndarray*

Calculates the receive filter of all users.

Returns The receive filter of all users. This is a numpy array of numpy arrays.

Return type np.ndarray

_calc_Uk_all_k_rev () → *numpy.ndarray*

Calculates the receive filter of all users for the reverse channel.

Returns

np.ndarray The receive filter of all users for the reverse channel. This is a numpy array of numpy arrays.

classmethod **_calc_Ukl** (*Hkk: numpy.ndarray, Vk: numpy.ndarray, Bkl: numpy.ndarray, l: int*) → *numpy.ndarray*

Calculates the Ukl matrix in equation (29) of [Cadambe2008].

Parameters

- **Hkk** (*np.ndarray*) – Channel from transmitter K to receiver K.
- **Vk** (*np.ndarray*) – Precoder of user k.
- **Bkl** (*np.ndarray*) – The previously calculates Bkl matrix in equation (28) of [Cadambe2008]
- **l** (*int*) – Index of the desired stream

Returns **Ukl** – The calculated Ukl matrix. This is a 2D numpy array (with self.Nr[k] rows and a single column).

Return type np.ndarray

`_updateF()` → `None`
Update the precoders.

Notes

This method is called in the `IterativeIASolverBaseClass._step()` method.

See also:

`IterativeIASolverBaseClass._step()`

`_updateW()` → `None`
Update the receive filters.

Notes

This method is called in the `IterativeIASolverBaseClass._step()` method.

See also:

`IterativeIASolverBaseClass._step()`

class `pyphysim.ia.algorithms.MinLeakageIASolver` (`multiUserChannel`: `py-`
`physim.channels.multiusers.MultiUserChannelMatrix`)
Bases: `pyphysim.ia.algorithms.IterativeIASolverBaseClass`

Implements the Minimum Leakage Interference Alignment algorithm as described in the paper “Approaching the Capacity of Wireless Networks through Distributed Interference Alignment [Cadambe2008]”.

Parameters `multiUserChannel` (`muchannels.MultiUserChannelMatrix`) – The multiusers channel.

`_calc_Uk_all_k()` → `numpy.ndarray`
Calculates the receive filter of all users.

Returns The `Uk` array of each user. This is a 1D numpy array of numpy arrays.

Return type `np.ndarray`

`_calc_Uk_all_k_rev()` → `numpy.ndarray`
Calculates the receive filter of all users in the reverse network.

Returns The `Uk` array of each user. This is a 1D numpy array of numpy arrays.

Return type `np.ndarray`

`_updateF()` → `None`
Update the precoders.

Notes

This method is called in the `IterativeIASolverBaseClass._step()` method.

See also:

`IterativeIASolverBaseClass._step()`

`_updateW()` → `None`
Update the receive filters.

Notes

This method is called in the `IterativeIASolverBaseClass._step()` method.

See also:

`IterativeIASolverBaseClass._step()`

get_cost() → float

Get the Cost of the algorithm for the current iteration of the precoder.

For the Minimum Leakage Interference Alignment algorithm the cost is equivalent to the sum of the interference that all users see after applying the receive filter. That is,

$$C = \text{Tr}[H_{kk}^H]$$

Returns cost – The Cost of the algorithm for the current iteration of the precoder. This is a (real non-negative number).

Return type float

pyphysim.ia.iabase module

Module containing the base class for Interference Alignment (IA) Algorithms.

This module should probably only be imported in the other modules inside the ‘ia’ package that implement the IA algorithms.

class `pyphysim.ia.iabase.IASolverBaseClass` (`multiUserChannel:` `pyphysim.channels.multiuser.MultiUserChannelMatrix`)

Bases: `object`

Base class for all Interference Alignment Algorithms.

At least the `_updateW`, `_updateF` and `solve` methods must be implemented in the subclasses of `IASolverBaseClass`, where the `solve` method uses the `_updateW` and `_updateF` methods in its implementation.

The implementation of the `_updateW` method should call the `_clear_receive_filter` method in the beginning and after that set either the `_W` or the `_W_H` variables with the correct value.

The implementation of the `_updateF` method should call the `clear_precoder_filter` in the beginning and after that set `_W` variable with the correct precoder (normalized to have a Frobenius norm equal to one).

The implementation of the `_updateF` method must set the `_F` variable with the correct value.

Another method that can be implemented is the `get_cost` method. It should return the cost of the current IA solution. What is considered “the cost” varies from one IA algorithm to another, but should always be a real non-negative number. If `get_cost` is not implemented a value of -1 is returned.

Parameters `multiUserChannel` (`muchannels.MultiUserChannelMatrix`) – The multiuser channel.

property `F`

Transmit precoder of all users.

Returns The precoders of all users (a 1D numpy array of 2D numpy arrays).

Return type `np.ndarray`

property `K`

The number of users.

Returns `K` – The number of users.

Return type `int`

property Nr

Number of receive antennas of all users.

Returns Nr – Number of receive antennas of all users.

Return type `np.ndarray`

property Ns

Number of streams of all users.

Returns Ns – Number of streams of all users.

Return type `np.ndarray`

property Nt

Number of transmit antennas of all users.

Returns Nt – Number of transmit antennas of all users.

Return type `np.ndarray`

property P

Transmit power of all users.

Returns The power of all users.

Return type `np.ndarray`

property W

Receive filter of all users.

Returns The receive filter of all users. (a 1D numpy array of 2D numpy arrays).

Return type `np.ndarray`

property W_H

Get method for the W_H property.

Returns The conjugate of the receive filter of all users. (a 1D numpy array of 2D numpy arrays).

Return type `np.ndarray`

`_calc_Bkl_cov_matrix_all_1` (*k*: `int`, *noise_power*: `Optional[float] = None`) → `numpy.ndarray`

Calculates the interference-plus-noise covariance matrix for all streams at receiver *k* according to equation (28) in [Cadambe2008].

The interference-plus-noise covariance matrix for stream *l* of user *k* is given by Equation (28) in [Cadambe2008], which is reproduced below

$$[k]_l = \sum_{j=1}^K \frac{P[j]}{d[j]} \sum_{d=1}^{d[j]} \mathbf{[k]_j[j]_{*l}}^\dagger \mathbf{[k]_j[j]_{*l}} - \frac{P[k]}{d[k]} \mathbf{[k]_{*l}}^\dagger \mathbf{[k]_{*l}} + N[k]$$

where $P[k]$ is the transmit power of transmitter *k*, $d[k]$ is the number of degrees of freedom of user *k*, $[k]_j$ is the channel between transmitter *j* and receiver *k*, $_{*l}$ is the *l*-th column of the precoder of user *k* and $N[k]$ is an identity matrix with size equal to the number of receive antennas of receiver *k*.

Parameters

- **k** (`int`) – Index of the desired user.
- **noise_power** (`float`) – Noise power (variance).

Returns Bkl – Covariance matrix of all streams of user k . Each element of the returned 1D numpy array is a 2D numpy complex array corresponding to the covariance matrix of one stream of user k .

Return type np.ndarray

Notes

To be simple, a function that returns the covariance matrix of only a single stream “1” of the desired user “ k ” could be implemented, but in the order to calculate the max SINR algorithm we need the covariance matrix of all streams and returning them in single function as is done here allows us to calculate the first part in equation (28) of [Cadambe2008] only once, since it is the same for all streams.

_calc_Bkl_cov_matrix_first_part (k : int) → numpy.ndarray

Calculates the first part in the equation of the Blk covariance matrix in equation (28) of [Cadambe2008].

The first part is given by

$$\sum_{j=1}^K \frac{P[j]}{d[j]} \sum_{d=1}^{d[j]} \begin{matrix} [kj] & [j] \\ \star d & \star d \end{matrix} [j]^\dagger [kj]^\dagger$$

Note that it only depends on the value of k .

Parameters k (int) – Index of the desired user.

Returns Bkl_first_part – First part in equation (28) of [Cadambe2008].

Return type np.ndarray

_calc_Bkl_cov_matrix_second_part (k : int, l : int) → numpy.ndarray

Calculates the second part in the equation of the Blk covariance matrix in equation (28) of [Cadambe2008] (note that it does not include the identity matrix).

The second part is given by

$$\frac{P[k]}{d[k]} \begin{matrix} [kk] \\ \star l \end{matrix} \begin{matrix} [k] & [k] \\ [k] & [k] \end{matrix}^\dagger [kk]^\dagger$$

Parameters

- **k** (int) – Index of the desired user.
- **l** (int) – Index of the desired stream.

Returns second_part – Second part in equation (28) of [Cadambe2008].

Return type np.ndarray

_calc_SINR_k (k : int, Bkl_all_l : Sequence[numpy.ndarray]) → numpy.ndarray

Calculates the SINR of all streams of user ‘ k ’.

Parameters

- **k** (int) – Index of the desired user.
- **Bkl_all_l** (list[np.ndarray] | nd.ndarray) – A sequence (1D numpy array, a list, etc) of 2D numpy arrays corresponding to the Bkl matrices for all ‘1’s.

Returns `SINR_k` – The SINR for the different streams of user k .

Return type `np.ndarray`

`_calc_equivalent_channel(k: int) → numpy.ndarray`

Calculates the equivalent channel for user k considering the effect of the precoder (including transmit power), the actual channel, and the receive filter (without power compensation).

Parameters `k (int)` – The index of the desired user.

Returns `Hk_eq` – The equivalent channel.

Return type `np.ndarray`

Notes

This method is used only internally in order to calculate the “W” get property so that the returned filter W compensates the effect of the direct channel.

`_clear_precoder_filter() → None`

Clear the precoder filter.

This should be called in the beginning of the implementation of the `_updateF` method in subclasses.

`_clear_receive_filter() → None`

Clear the receive filter.

This should be called in the beginning of the implementation of the `_updateW` method in subclasses.

`_get_channel(k: int, l: int) → numpy.ndarray`

Get the channel from transmitter l to receiver k .

Parameters

- `l (int)` – Transmitting user.
- `k (int)` – Receiving user.

Returns `H` – The channel matrix between transmitter l and receiver k .

Return type `np.ndarray`

`_get_channel_rev(k: int, l: int) → numpy.ndarray`

Get the channel from transmitter l to receiver k in the reverse network.

Let the matrix $_{kl}$ be the channel matrix between the transmitter l to receiver k in the direct network. The channel matrix between the transmitter l to receiver k in the reverse network, denoted as \leftarrow_{kl} , is then given by $\leftarrow_{kl} = \dagger_{lk}$ where \dagger is the conjugate transpose of \cdot .

Parameters

- `l (int)` – Transmitting user of the reverse network.
- `k (int)` – Receiving user of the reverse network.

Returns `H` – The channel matrix between transmitter l and receiver k in the reverse network.

Return type `np.ndarray`

Notes

See Section III of [Cadambe2008] for details.

calc_Q (*k*: *int*) → *numpy.ndarray*

Calculates the interference covariance matrix at the *k*-th receiver.

The interference covariance matrix at the *k*-th receiver, *k*, is given by

$$\mathbf{Q}_k = \sum_{j=1, j \neq k}^K \frac{P_j}{N_{s_j}} \mathbf{H}_{j,k} \mathbf{H}_{j,k}^H$$

where P_j is the transmit power of transmitter *j*, and N_{s_j} is the number of streams for user *j*.

Parameters *k* (*int*) – Index of the desired receiver.

Returns **Q_k** – The interference covariance matrix at receiver *k*.

Return type *np.ndarray*

Notes

This is impacted by the self.P attribute.

calc_Q_rev (*k*: *int*) → *numpy.ndarray*

Calculates the interference covariance matrix at the *k*-th receiver in the reverse network.

Parameters *k* (*int*) – Index of the desired receiver.

Returns **Q_{k_rev}** – The interference covariance matrix at receiver *k* in the reverse network.

Return type *np.ndarray*

See also:

calc_Q()

calc_SINR () → *numpy.ndarray*

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the noise_var property, which, if not explicitly set, will use the noise_var property of the multiuserchannel object.

Returns **SINRs** – The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats).

Return type *np.ndarray*

calc_SINR_in_dB () → *numpy.ndarray*

Calculates the SINR values (in dB scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the noise_var property, which, if not explicitly set, will use the noise_var property of the multiuserchannel object.

Returns **SINRs** – The SINR (in dB scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats).

Return type *np.ndarray*

calc_SINR_old() → `numpy.ndarray`

Calculates the SINR values (in linear scale) of all streams of all users with the current IA solution.

The noise variance used will be the value of the `noise_var` property, which, if not explicitly set, will use the `noise_var` property of the `multiuserchannel` object.

This method is deprecated since it's not the correct way to calculate the SINR. Use the `calc_SINR` method instead.

Returns SINRs – The SINR (in linear scale) of all streams of all users. This is a 1D numpy array of 1D numpy arrays (of floats).

Return type `np.ndarray`

calc_remaining_interference_percentage (*k*: `int`, *Qk*: *Optional*[`numpy.ndarray`] = *None*) → `float`

Calculates the percentage of the interference in the desired signal space according to equation (30) in [Cadambe2008].

The percentage p_k of the interference in the desired signal space is given by

$$p_k = \frac{\sum_{j=1}^{N_s[k]} \lambda_j[k]}{Tr[k]}$$

where $\lambda_j[\cdot]$ denotes the j -th smallest eigenvalue of \cdot .

Parameters

- **k** (`int`) – The index of the desired user.
- **Qk** (`np.ndarray`) – The covariance matrix of the remaining interference at receiver k . If not provided, it will be automatically calculated. In that case, the P attribute will also be taken into account if it is set.

Returns The percentage of the interference in the desired signal space.

Return type `float`

Notes

Qk must be a symmetric matrix so that its eigenvalues are real and positive (any covariance matrix is a symmetric matrix).

calc_sum_capacity() → `float`

Calculates the sum capacity of the current solution.

The SINRs are estimated and applied to the Shannon capacity formula

Returns The sum capacity of the current solution.

Return type `float`

clear() → `None`

Clear the IA Solver object.

All member attributes that are updated during the solve method, such as the precoder and receive filters, will be cleared. The other attributes that correspond to “configuration” such as the channel object won't be changed.

Notes

You should overwrite this method in subclasses that pass parameters to the `__init__` method, since here we call `__init__` without arguments which is probably not what you want.

property `full_F`

Transmit precoder of all users.

Returns The precoders of all users (a 1D numpy array of 2D numpy arrays).

Return type `np.ndarray`

property `full_W`

Get method for the `full_W` property.

The `full_W` property returns the equivalent filter of the IA filter plus the post processing filter.

Returns the equivalent filter of the IA filter plus the post processing filter.

Return type `np.ndarray`

property `full_W_H`

Get method for the `full_W_H` property.

The `full_W_H` property returns the equivalent filter of the IA filter plus the post processing filter.

Returns The equivalent filter of the IA filter plus the post processing filter.

Return type `np.ndarray`

`get_cost()` → `float`

Get the current cost of the IA Solution.

This method should be implemented in subclasses and return a number greater than or equal to zero..

Returns `cost` – The Cost of the current IA solution (a real non-negative number).

Return type `float`

property `noise_var`

Get method for the `noise_var` property.

Returns The noise variance (a real non-negative number).

Return type `float`

`randomizeF(Ns: Union[int, List[int], Sequence[int]], P: Optional[numpy.ndarray] = None) → None`

Generates a random precoder for each user.

Parameters

- **Ns** (`int` | `list[int]` | `np.ndarray`) – Number of streams of each user.
- **P** (`np.ndarray`, `optional`) – Power of each user. If not provided, a value of 1 will be used for each user.

`set_precoders(F: Optional[Sequence[numpy.ndarray]] = None, full_F: Optional[Sequence[numpy.ndarray]] = None, P: Optional[numpy.ndarray] = None) → None`

Set the precoders of each user.

Either `F` or `full_F` (or both of them) must be provided.

If only `full_F` is provided then the value of `F` will be calculated from `full_F`.

In any case, the value of `self.Ns` will be updated according to the dimensions of the `F` or `full_F`.

Parameters

- **F** (*np.ndarray* | *list[[np.ndarray](#)]*, *optional*) – A numpy array where each element is the (normalized) precoder (a 2D numpy array) of one user.
- **full_F** (*np.ndarray* | *list[[np.ndarray](#)]*, *optional*) – A numpy array where each element is the precoder (a 2D numpy array) of one user.
- **P** (*np.ndarray*, *optional*) – The maximum transmit power. If not provided the current value of self.P will be kept as it is.

set_receive_filters (*W_H*: *Optional[Sequence[[numpy.ndarray](#)]]* = *None*, *W*: *Optional[Sequence[[numpy.ndarray](#)]]* = *None*) → *None*

Set the receive filters.

You only need to pass either *W_H* or *W*, but not both of them, since one is calculated from the other.

Parameters

- **W_H** (*np.ndarray* | *list[[np.ndarray](#)]*) – A numpy array where each element is the receive filter (a 2D numpy array) of one user. This is a 1D numpy array of 2D numpy arrays.
- **W** (*np.ndarray* | *list[[np.ndarray](#)]*) – A numpy array where each element is the receive filter (a 2D numpy array) of one user. This is a 1D numpy array of 2D numpy arrays.

abstract solve (*Ns*: *Union[int, [numpy.ndarray](#)]*, *P*: *Optional[[numpy.ndarray](#)] = None*) → *Any*

Find the IA solution.

This method must be implemented in a subclass and should updates the ‘F’ and ‘W’ member variables.

Parameters

- **Ns** (*int* | *np.ndarray*) – Number of streams of each user.
- **P** (*np.ndarray*) – Power of each user. If not provided, a value of 1 will be used for each user.

Notes

This function should be implemented in the derived classes

Module contents

Package with Interference Alignment (IA) algorithms.

Note that all IA algorithms require the channel object and any change to the channel object must be performed before calling the *solve* method of the IA algorithm object. This includes generating the channel and setting the noise variance.

pyphysim.mimo package

Submodules

pyphysim.mimo.mimo module

Module implementing different MIMO schemes.

Each MIMO scheme is implemented as a class inheriting from [MimoBase](#) and implements at least the methods *encode*, *decode* and *getNumberOfLayers*.

class `pyphysim.mimo.mimo.Alamouti` (*channel: Optional[numpy.ndarray] = None*)

Bases: `pyphysim.mimo.mimo.MimoBase`

MIMO class for the Alamouti scheme.

Parameters `channel` (*np.ndarray*) – MIMO channel matrix.

static `_calc_precoder` (*channel: numpy.ndarray*) → *numpy.ndarray*

Not defined.

There is no linear precoder for the Alamouti scheme and thus an exception is called if this method is ever called.

static `_calc_receive_filter` (*channel: numpy.ndarray, noise_var: Optional[float] = None*) → *numpy.ndarray*

Not defined.

There is no linear receive filter for the Alamouti scheme that can be directly applied to the received data. Thus, an exception is called if this method is ever called.

static `_decode` (*received_data: numpy.ndarray, channel: numpy.ndarray*) → *numpy.ndarray*

Perform the decoding of the `received_data` for the Alamouti scheme with the channel `channel`, but does not compensate for the power division among transmit antennas.

The idea is that the decode method will call `_decode` and perform the power compensation. This separation allows better code reuse.

Parameters

- **received_data** (*np.ndarray*) – Received data, which was encoded with the Alamouti scheme and corrupted by the channel `channel`.
- **channel** (*np.ndarray*) – MIMO channel matrix.

Returns `decoded_data` – The decoded data (without power compensating the power division performed during transmission).

Return type *np.ndarray*

See also:

`decode()`

static `_encode` (*transmit_data: numpy.ndarray*) → *numpy.ndarray*

Perform the Alamouti encoding, but without dividing the power among the transmit antennas.

The idea is that the encode method will call `_encode` and perform the power division. This separation allows better code reuse.

Parameters `transmit_data` (*np.ndarray*) – Data to be encoded by the Alamouti scheme.

Returns `encoded_data` – The encoded `transmit_data` (without dividing the power among transmit antennas).

Return type *np.ndarray*

See also:

`encode()`

calc_linear_SINRs (*noise_var: float*) → *numpy.ndarray*

Calculate the SINRs (in linear scale) of the multiple streams.

Parameters `noise_var` (*float*) – The noise variance.

Returns `sinrs` – The sinrs (in linear scale) of the multiple streams.

Return type `np.ndarray`

decode (*received_data*: `numpy.ndarray`) → `numpy.ndarray`

Perform the decoding of the *received_data* for the Alamouti scheme with the channel *channel*.

Parameters **received_data** (`np.ndarray`) – Received data, which was encoded with the Alamouti scheme and corrupted by the channel *channel*.

Returns **decoded_data** – The decoded data.

Return type `np.ndarray`

encode (*transmit_data*: `numpy.ndarray`) → `numpy.ndarray`

Perform the Alamouti encoding.

Parameters **transmit_data** (`np.ndarray`) – Data to be encoded by the Alamouti scheme.

Returns **encoded_data** – The encoded *transmit_data*.

Return type `np.ndarray`

getNumberOfLayers () → `int`

Get the number of layers of the Alamouti scheme.

The number of layers in the Alamouti scheme is always equal to one.

Returns **NI** – Number of layers of the Alamouti scheme, which is always one.

Return type `int`

set_channel_matrix (*channel*: `numpy.ndarray`) → `None`

Set the channel matrix.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix.

Returns

Return type `None`

class `pyphysim.mimo.mimo.Blast` (*channel*: `Optional[numpy.ndarray]` = `None`)

Bases: `pyphysim.mimo.mimo.MimoBase`

MIMO class for the BLAST scheme.

The receive filter used will depend on the noise variance (see the `set_noise_var()` method). If the noise variance is positive the MMSE filter will be used, otherwise noise variance will be ignored and the Zero-Forcing filter will be used.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix.

static **_calc_precoder** (*channel*: `numpy.ndarray`) → `numpy.ndarray`

Calculate the linear precoder for the BLAST scheme.

The BLAST scheme simply send the data through the multiple streams without any particular precoding. Therefore, its linear precoder is equivalent to an identity matrix.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix.

Returns **W** – The precoder that can be applied to the input data.

Return type `np.ndarray`

static **_calc_receive_filter** (*channel*: `numpy.ndarray`, *noise_var*: `Optional[float]` = `None`) → `numpy.ndarray`

Calculate the receive filter for the MIMO scheme, if there is any.

Parameters

- **channel** (*np.ndarray*) – MIMO channel matrix.
- **noise_var** (*float*) – The noise variance. If a value is provided then MMSE filter will be used. If it is not provided (or None is passes) then Zero Force filter will be used.

Returns **G_H** – The receive_filter that can be applied to the input data.

Return type *np.ndarray*

decode (*received_data: numpy.ndarray*) → *numpy.ndarray*

Decode the received data array.

Parameters **received_data** (*np.ndarray*) – Received data, which was encoded with the Blast scheme and corrupted by the channel *channel*.

Returns **decoded_data** – The decoded data.

Return type *np.ndarray*

encode (*transmit_data: numpy.ndarray*) → *numpy.ndarray*

Encode the transmit data array to be transmitted using the BLAST scheme.

Parameters **transmit_data** (*np.ndarray*) – A numpy array with a number of elements which is a multiple of the number of transmit antennas.

Returns **encoded_data** – The encoded *transmit_data*.

Return type *np.ndarray*

Raises **ValueError** – If the number of elements in *transmit_data* is not multiple of the number of transmit antennas.

getNumberOfLayers () → *int*

Get the number of layers of the Blast scheme.

Returns **Nl** – Number of layers of the MIMO scheme.

Return type *int*

set_channel_matrix (*channel: numpy.ndarray*) → *None*

Set the channel matrix.

Parameters **channel** (*np.ndarray*) – MIMO channel matrix.

set_noise_var (*noise_var: Optional[float]*) → *None*

Set the noise variance for the MMSE receive filter.

If noise_var is non-positive then the Zero-Force filter will be used instead.

Parameters **noise_var** (*float | None*) – Noise variance for the MMSE filter (if *noise_var* is positive). If *noise_var* is 0.0 or None then the Zero-Forcing filter will be used.

Returns

Return type *None*

class *pyphysim.mimo.mimo.GMDMimo* (*channel: Optional[numpy.ndarray] = None*)

Bases: *pyphysim.mimo.mimo.Blast*

MIMO class for the GMD based MIMO scheme.

Parameters **channel** (*np.ndarray*) – MIMO channel matrix.

static **_calc_precoder** (*channel: numpy.ndarray*) → *numpy.ndarray*

Calculate the linear precoder for the GMD scheme.

Parameters **channel** (*np.ndarray*) – MIMO channel matrix with dimension (1, Nt).

Returns **W** – The precoder that can be applied to the input data.

Return type `np.ndarray`

static `_calc_receive_filter` (*channel*: `numpy.ndarray`, *noise_var*: `Optional[float] = None`)
→ `numpy.ndarray`

Calculate the receive filter for the MRT scheme.

Parameters

- **channel** (`np.ndarray`) – MIMO channel matrix.
- **noise_var** (`float`) – The noise variance.

Returns **G_H** – The receive_filter that can be applied to the input data.

Return type `np.ndarray`

decode (*received_data*: `numpy.ndarray`) → `numpy.ndarray`

Perform the decoding of the received_data for the GMD MIMO.

Parameters **received_data** (`np.ndarray`) – Received data, which was encoded with the Alamouti scheme and corrupted by the channel *channel*.

Returns **decoded_data** – The decoded data.

Return type `np.ndarray`

encode (*transmit_data*: `numpy.ndarray`) → `numpy.ndarray`

Encode the transmit data array to be transmitted using the GMD MIMO scheme.

The GMD MIMO scheme is based on the Geometric Mean Decomposition (GMD) of the channel. The channel is decomposed into $H = QR^H$, where R is an upper triangular matrix with all diagonal elements being equal to the geometric mean of the singular values of the channel matrix H .

corresponds to using the ‘U’ and ‘V’ matrices from the SVD decomposition of the channel as the precoder and receive filter.

Parameters **transmit_data** (`np.ndarray`) – A numpy array with the data to be transmitted.

Returns **encoded_data** – The encoded *transmit_data*.

Return type `np.ndarray`

class `pyphysim.mimo.mimo.MRC` (*channel*: `Optional[numpy.ndarray] = None`)

Bases: `pyphysim.mimo.mimo.Blast`

MIMO class for the MRC scheme.

The receive filter used will depend on the noise variance (see the `set_noise_var()` method). If the noise variance is positive the MMSE filter will be used, otherwise noise variance will be ignored and the Zero-Forcing filter will be used.

The receive filter in the *Blast* class already does the maximum ratio combining. Therefore, this MRC class simply inherits from the Blast class and only exists for completion.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix.

set_channel_matrix (*channel*: `numpy.ndarray`) → `None`

Set the channel matrix.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix. The MRC MIMO scheme is defined for the scenario with multiple receive antennas and a single receive antenna. If channel is 1D assume that the number of transmit antennas is equal to 1.

class `pyphysim.mimo.mimo.MRT` (*channel: Optional[numpy.ndarray] = None*)

Bases: `pyphysim.mimo.mimo.MisoBase`

MIMO class for the MRT scheme.

The number of streams for the MRT scheme is always equal to one, but it still employs multiple transmit antennas.

If *channel* is not provided you need to call the `set_channel_matrix` method before calling the other methods.

Parameters `channel` (*np.ndarray*) – MISO channel vector. It must be a 1D numpy array, where the number of receive antennas is assumed to be equal to 1.

static `_calc_precoder` (*channel: numpy.ndarray*) → *numpy.ndarray*

Calculate the linear precoder for the MRT scheme.

The MRT scheme corresponds to multiplying the symbol from each transmit antenna with a complex number corresponding to the inverse of the phase of the channel so as to ensure that the signals add constructively at the receiver. This also means that the MRT scheme only be applied to scenarios with a single receive antenna.

Parameters `channel` (*np.ndarray*) – MIMO channel matrix with dimension (1, Nt).

Returns `W` – The precoder that can be applied to the input data.

Return type *np.ndarray*

static `_calc_receive_filter` (*channel: numpy.ndarray, noise_var: Optional[float] = None*) → *numpy.ndarray*

Calculate the receive filter for the MRT scheme.

Parameters

- `channel` (*np.ndarray*) – MIMO channel matrix.
- `noise_var` (*float*) – The noise variance.

Returns `G_H` – The receive_filter that can be applied to the input data.

Return type *np.ndarray*

decode (*received_data: numpy.ndarray*) → *numpy.ndarray*

Decode the received data array.

Parameters `received_data` (*np.ndarray*) – Received data, which was encoded with the MRT scheme and corrupted by the channel *channel*.

Returns `decoded_data` – The decoded data.

Return type *np.ndarray*

encode (*transmit_data: numpy.ndarray*) → *numpy.ndarray*

Encode the transmit data array to be transmitted using the MRT scheme.

The MRT scheme corresponds to multiplying the symbol from each transmit antenna with a complex number corresponding to the inverse of the phase of the channel so as to ensure that the signals add constructively at the receiver. This also means that the MRT scheme only be applied to scenarios with a single receive antenna.

Parameters `transmit_data` (*np.ndarray*) – A numpy array with the data to be transmitted.

Returns `encoded_data` – The encoded *transmit_data*.

Return type *np.ndarray*

```
class pyphysim.mimo.mimo.MimoBase (channel: Optional[numpy.ndarray] = None)
```

Bases: `object`

Base Class for MIMO schemes.

All subclasses must implement at least the following methods:

- `getNumberOfLayers()`: Should return the number of layers of that specific MIMO scheme
- `encode()`: The encode method must perform everything executed at the transmitter for that specific MIMO scheme. This also include the power division among the transmit antennas.
- `decode()`: Analogous to the encode method, the decode method must perform everything performed at the receiver.

If possible, subclasses should implement the `_calc_precoder` and `_calc_receive_filter` static methods and use them in the implementation of `encode` and `decode`. This will allow using the `calc_linear_SINRs` and `calc_SINRs` methods to calculate the post processing SINRs. Note that calling the `_calcZeroForceFilter` and `_calcMMSEFilter` methods in the implementation of the receive filter calculation can be useful.

If you can't implement the `_calc_precoder` and `_calc_receive_filter` static methods` (because there is no linear precoder or receive filter for the MIMO scheme in the subclass, for instance), then you should implement the `calc_linear_SINRs` method in the subclass instead.

Parameters `channel` (`np.ndarray` | `None`) – MIMO channel matrix. This should be a 1D or 2D numpy array. The allowed dimensions will depend on the particular MIMO scheme implemented in a subclass.

property `Nr`

Get the number of receive antennas

Returns The number of receive antennas.

Return type `int`

property `Nt`

Get the number of transmit antennas

Returns The number of transmit antennas.

Return type `int`

```
static _calcMMSEFilter (channel: numpy.ndarray, noise_var: float) → numpy.ndarray
```

Calculates the MMSE filter to cancel the inter-stream interference.

Parameters

- `channel` (`np.ndarray`) – MIMO channel matrix.
- `noise_var` (`float`) – Noise variance.

Returns `W` – The MMSE receive filter.

Return type `np.ndarray`

```
static _calcZeroForceFilter (channel: numpy.ndarray) → numpy.ndarray
```

Calculates the Zero-Force filter to cancel the inter-stream interference.

Parameters `channel` (`np.ndarray`) – MIMO channel matrix.

Returns `W` – The Zero-Forcing receive filter.

Return type `np.ndarray`

Notes

The Zero-Force filter basically corresponds to the pseudo-inverse of the channel matrix.

static `_calc_precoder` (*channel*: *numpy.ndarray*) → *numpy.ndarray*

Calculate the linear precoder for the MIMO scheme, if there is any.

Parameters *channel* (*np.ndarray*) – MIMO channel matrix.

Returns *W* – The precoder that can be applied to the input data.

Return type *np.ndarray*

static `_calc_receive_filter` (*channel*: *numpy.ndarray*, *noise_var*: *Optional[float] = None*) → *numpy.ndarray*

Calculate the receive filter for the MIMO scheme, if there is any.

Parameters

- *channel* (*np.ndarray*) – MIMO channel matrix.
- *noise_var* (*float*) – The noise variance.

Returns *G_H* – The receive_filter that can be applied to the input data.

Return type *np.ndarray*

calc_SINRs (*noise_var*: *float*) → *numpy.ndarray*

Calculate the SINRs (in dB) of the multiple streams.

Parameters *noise_var* (*float*) – The noise variance.

Returns *SINRs* – The SINRs (in dB) of the multiple streams.

Return type *np.ndarray*

calc_linear_SINRs (*noise_var*: *float*) → *numpy.ndarray*

Calculate the SINRs (in linear scale) of the multiple streams.

Parameters *noise_var* (*float*) – The noise variance.

Returns *sinrs* – The sinrs (in linear scale) of the multiple streams.

Return type *np.ndarray*

abstract `decode` (*received_data*: *numpy.ndarray*) → *numpy.ndarray*

Method to decode the transmit data array to be transmitted using some MIMO scheme. This method must be implemented in a subclass.

Parameters *received_data* (*np.ndarray*) – The received data.

Returns *decoded_data* – The decoded data.

Return type *np.ndarray*

abstract `encode` (*transmit_data*: *numpy.ndarray*) → *numpy.ndarray*

Method to encode the transmit data array to be transmitted using some MIMO scheme. This method must be implemented in a subclass.

Parameters *transmit_data* (*np.ndarray*) – The data to be transmitted.

Returns *encoded_data* – The encoded *transmit_data*.

Return type *np.ndarray*

abstract `getNumberOfLayers` () → *int*

Get the number of layers of the MIMO scheme.

Notes

This method must be implemented in each subclass of *MimoBase*.

Returns The number of layers.

Return type `int`

set_channel_matrix (*channel*: `numpy.ndarray`) → `None`

Set the channel matrix.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix. This should be a 1D or 2D numpy array. The allowed dimensions will depend on the particular MIMO scheme implemented in a subclass.

class `pyphysim.mimo.mimo.MisoBase` (*channel*: `Optional[numpy.ndarray] = None`)

Bases: `pyphysim.mimo.mimo.MimoBase`

Base Class for MISO schemes.

All subclasses must implement at least the following methods:

- `MimoBase.encode()`: The encode method must perform everything executed at the transmitter for that specific MIMO scheme. This also include the power division among the transmit antennas.
- `MimoBase.decode()`: Analogous to the encode method, the decode method must perform everything performed at the receiver.

Other optional methods that might be useful implementing in subclasses are the `_calc_precoder` and `_calc_receive_filter` methods.

Parameters **channel** (`np.ndarray`) – MISO channel matrix/vector. MISO schemes are defined for scenarios with multiple transmit antennas and a single receive antenna. If *channel* is 2D, then the first dimension size must be equal to 1.

getNumberOfLayers () → `int`

Get the number of layers of the MISO scheme.

Because a MISO scheme only has one receive antenna then the number of layers is always equal to 1.

Returns The number of layers.

Return type `int`

set_channel_matrix (*channel*: `numpy.ndarray`) → `None`

Set the channel matrix.

Parameters **channel** (`np.ndarray`) – MISO channel vector. A MISO scheme is defined for the scenario with multiple transmit antennas and a single receive antenna. If *channel* is 2D then the first dimension size must be equal to 1.

Returns

Return type `None`

class `pyphysim.mimo.mimo.SVDMimo` (*channel*: `Optional[numpy.ndarray] = None`)

Bases: `pyphysim.mimo.mimo.Blast`

MIMO class for the SVD MIMO scheme.

Parameters **channel** (`np.ndarray`) – MIMO channel matrix.

static `_calc_precoder` (*channel*: `numpy.ndarray`) → `numpy.ndarray`

Calculate the linear precoder for the SVD MIMO scheme.

The SVD MIMO scheme employs as precoder the right singular matrix from SVD (Singular Value Decomposition) of the channel.

Parameters `channel` (*np.ndarray*) – MIMO channel matrix with dimension (1, Nt).

Returns `W` – The precoder that can be applied to the input data.

Return type *np.ndarray*

static `_calc_receive_filter` (*channel: numpy.ndarray, noise_var: Optional[float] = None*)
→ *numpy.ndarray*

Calculate the receive filter for the SVD MIMO scheme.

Parameters

- `channel` (*np.ndarray*) – MIMO channel matrix.
- `noise_var` (*float*) – The noise variance.

Returns `G_H` – The receive_filter that can be applied to the input data.

Return type *np.ndarray*

decode (*received_data: numpy.ndarray*) → *numpy.ndarray*

Perform the decoding of the received_data for the SVD MIMO scheme with the channel *channel*.

Parameters `received_data` (*np.ndarray*) – Received data, which was encoded with the Alamouti scheme and corrupted by the channel *channel*.

Returns `decoded_data` – The decoded data.

Return type *np.ndarray*

encode (*transmit_data: numpy.ndarray*) → *numpy.ndarray*

Encode the transmit data array to be transmitted using the SVD MIMO scheme.

The SVD MIMO scheme corresponds to using the ‘U’ and ‘V’ matrices from the SVD decomposition of the channel as the precoder and receive filter.

Parameters `transmit_data` (*np.ndarray*) – A numpy array with the data to be transmitted.

Returns `encoded_data` – The encoded *transmit_data*.

Return type *np.ndarray*

Module contents

pyphysim.modulators package

Submodules

pyphysim.modulators.fundamental module

Module with class for some fundamental modulators, such as PSK and M-QAM.

All fundamental modulators inherit from the *Modulator* class and should call the *self.setConstellation* method in their *__init__* method, as well as implement the *calcTheoreticalSER* and *calcTheoreticalBER* methods.

class `pyphysim.modulators.fundamental.BPSK`

Bases: *pyphysim.modulators.fundamental.Modulator*

BPSK Class

calcTheoreticalBER (*SNR: NumberOrArray*) → *NumberOrArray*

Calculates the theoretical (approximation) bit error rate for the BPSK scheme.

Parameters *SNR* (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns *BER* – The theoretical bit error rate.

Return type *float* | *np.ndarray*

calcTheoreticalSER (*SNR: NumberOrArray*) → *NumberOrArray*

Calculates the theoretical (approximation) symbol error rate for the BPSK scheme.

Parameters *SNR* (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns *SER* – The theoretical symbol error rate.

Return type *float* | *np.ndarray*

demodulate (*receivedData: numpy.ndarray*) → *numpy.ndarray*

Demodulate the data.

Parameters *receivedData* (*np.ndarray*) – Data to be demodulated.

Returns *demodulated_data* – The demodulated data.

Return type *np.ndarray*

modulate (*inputData: numpy.ndarray*) → *numpy.ndarray*

Modulate the input data (decimal data).

Parameters *inputData* (*np.ndarray*) – Data to be modulated.

Returns *modulated_data* – The modulated data

Return type *np.ndarray*

Raises *ValueError* – If *inputData* has any invalid value such as values greater than *self._M - 1*. Note that *inputData* should not have negative values but no check is done for this.

property name

Get the name property.

Returns The name of the modulator.

Return type *str*

class *pyphysim.modulators.fundamental.Modulator*

Bases: *object*

Base class for digital modulators.

The derived classes need to at least call *setConstellation* to set the constellation in their constructors as well as implement *calcTheoreticalSER* and *calcTheoreticalBER*.

Examples

```
>>> np.set_printoptions(linewidth=70)
>>> constellation = np.array([1 + 1j, -1 + 1j, -1 - 1j, 1 - 1j])
>>> m=Modulator()
>>> m.setConstellation(constellation)
>>> m.symbols
array([ 1.+1.j, -1.+1.j, -1.-1.j,  1.-1.j])
>>> m.M
4
```

(continues on next page)

(continued from previous page)

```

>>> m.K
2.0
>>> m
4-Modulator object
>>> m.modulate(np.array([0, 0, 3, 3, 1, 3, 3, 3, 2, 2]))
array([ 1.+1.j,  1.+1.j,  1.-1.j,  1.-1.j, -1.+1.j,  1.-1.j,  1.-1.j,
        1.-1.j, -1.-1.j, -1.-1.j])

>>> m.demodulate(np.array([ 1. + 1.j, 1. + 1.j, 1. - 1.j, 1. - 1.j,
→      - 1. + 1.j, 1. - 1.j, 1. - 1.j, 1. - 1.j,
→      - 1. - 1.j, - 1. - 1.j]))
array([0, 0, 3, 3, 1, 3, 3, 3, 2, 2])

```

property K

Get method for the K property.

The K property corresponds to the number of bits represented by each symbol in the constellation. It is equal to $\log_2(M)$, where M is the constellation size.

See also:

[M](#)

property M

Get method for the M property.

The M property corresponds to the number of symbols in the constellation.

See also:

[K](#)

calcTheoreticalBER (*SNR: NumberOrArray*) → NumberOrArray

Calculates the theoretical bit error rate.

Parameters *SNR* (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns *BER* – The theoretical bit error rate.

Return type *float* | *np.ndarray*

See also:

[calcTheoreticalSER\(\)](#), [calcTheoreticalPER\(\)](#)

Notes

This function should be implemented in the derived classes

calcTheoreticalPER (*SNR: NumberOrArray*, *packet_length: int*) → NumberOrArray

Calculates the theoretical package error rate.

A package is a group of bits, where if a single bit is in error then the whole package is considered to be in error.

The package error rate (PER) is a direct mapping of the bit error rate (BER), such that

$$PER = 1 - (1 - BER)^L$$

where L is the `packet_length`.

Parameters

- **SNR** (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).
- **packet_length** (*int*) – The package length. That is, the number of bits in each package.

Returns **PER** – The theoretical package error rate.

Return type *float* | *np.ndarray*

See also:

calcTheoreticalBER(), *calcTheoreticalSER()*, *calcTheoreticalSpectralEfficiency()*

calcTheoreticalSER (*SNR: NumberOrArray*) → *NumberOrArray*

Calculates the theoretical symbol error rate.

Parameters **SNR** (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns **SER** – The theoretical symbol error rate.

Return type *float* | *np.ndarray*

See also:

calcTheoreticalBER(), *calcTheoreticalPER()*

Notes

This function should be implemented in the derived classes

calcTheoreticalSpectralEfficiency (*SNR: NumberOrArray*, *packet_length: Optional[int] = None*) → *NumberOrArray*

Calculates the theoretical spectral efficiency.

If there was no error in the transmission, the spectral efficiency would be equal to the K property, that is, equal to the number of bits represented by each symbol in the constellation. However, due to bit errors the effective spectral efficiency will be lower.

The *calcTheoreticalSpectralEfficiency* method calculates the effective spectral efficiency from the K property and the package error rate (PER) for the given SNR and packet_length 'L', such that

$$se = K * (1 - PER)$$

Parameters

- **SNR** (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).
- **packet_length** (*int*, *optional*) – The package length. That is, the number of bits in each package.

Returns **se** – The theoretical spectral efficiency.

Return type *float* | *np.ndarray*

See also:

calcTheoreticalBER(), *calcTheoreticalPER()*, *K()*

demodulate (*receivedData: numpy.ndarray*) → *numpy.ndarray*

Demodulate the data.

Parameters **receivedData** (*np.ndarray*) – Data to be demodulated.

Returns **demodulated_data** – The demodulated data.

Return type np.ndarray

modulate (*inputData*: Union[int, numpy.ndarray]) → numpy.ndarray

Modulate the input data (decimal data).

Parameters *inputData* (np.ndarray | int) – Data to be modulated.

Returns *modulated_data* – The modulated data

Return type np.ndarray

Raises **ValueError** – If inputData has any invalid value such as values greater than self._M - 1. Note that inputData should not have negative values but no check is done for this.

property name

Get method for the 'name' property.

Returns The name of the modulator.

Return type str

plotConstellation () → None

Plot the constellation (in a scatter plot).

setConstellation (*symbols*: numpy.ndarray) → None

Set the constellation of the modulator.

This function should be called in the constructor of the derived classes.

Parameters *symbols* (np.ndarray) – A an numpy array with the symbol table.

class pyphysim.modulators.fundamental.PSK (*M*: int, *phaseOffset*: float = 0)

Bases: *pyphysim.modulators.fundamental.Modulator*

PSK Class

static **_createConstellation** (*M*: int, *phaseOffset*: float) → numpy.ndarray

Generates the Constellation for the PSK modulation scheme.

Parameters

- **M** (int) – The modulation cardinality
- **phaseOffset** (float) – A phase offset (in radians) to be applied to the PSK constellation.

Returns *symbols* – The PSK constellation with the desired cardinality and phase offset.

Return type np.ndarray

calcTheoreticalBER (*SNR*: NumberOrArray) → NumberOrArray

Calculates the theoretical (approximation) bit error rate for the M-PSK scheme using Gray coding.

Parameters *SNR* (float | np.ndarray) – Signal-to-noise-value (in dB).

Returns *BER* – The theoretical bit error rate.

Return type float | np.ndarray

calcTheoreticalSER (*SNR*: NumberOrArray) → NumberOrArray

Calculates the theoretical (approximation for high M and high SNR) symbol error rate for the M-PSK scheme.

Parameters *SNR* (float | np.ndarray) – Signal-to-noise-value (in dB).

Returns *SER* – The theoretical symbol error rate.

Return type float | np.ndarray

setPhaseOffset (*phaseOffset: float*) → None

Set a new phase offset for the constellation

Parameters **phaseOffset** (*float*) – A phase offset (in radians) to be applied to the PSK constellation.

class pyphysim.modulators.fundamental.QAM(*M: int*)

Bases: *pyphysim.modulators.fundamental.Modulator*

QAM Class

_calcTheoreticalSingleCarrierErrorRate (*SNR: NumberOrArray*) → NumberOrArray

Calculates the theoretical (approximation) error rate of a single carrier in the QAM system (QAM has two carriers).

Parameters **SNR** (*float | np.ndarray*) – Signal-to-noise-value (in dB).

Returns **Psc** – The theoretical single carrier error rate.

Return type float | np.ndarray

Notes

This method is used in the *calcTheoreticalSER()* implementation.

See also:

calcTheoreticalSER()

static **_calculateGrayMappingIndexQAM** (*L: int*) → *numpy.ndarray*

Calculates the indexes that should be applied to the constellation created by *_createConstellation* in order to correspond to Gray mapping.

Notice that the square M-QAM constellation is a matrix of dimension $L \times L$, where L is the square root of M . Since the constellation was generated without taking into account the Gray mapping, then we need to reorder the generated constellation and this function calculates the indexes that can be applied to the original constellation in order to do exactly that.

As an example, for the 16-QAM modulation the indexes can be organized (row order) in the matrix below

| / | 00 | 01 | 11 | 10 |
|----|------|------|------|------|
| 00 | 0000 | 0001 | 0011 | 0010 |
| 01 | 0100 | 0101 | 0111 | 0110 |
| 11 | 1100 | 1101 | 1111 | 1110 |
| 10 | 1000 | 1001 | 1011 | 1010 |

This is equivalent to concatenate a Gray mapping for the row with a Gray mapping for the column, and the corresponding indexes are [0, 1, 3, 2, 4, 5, 7, 6, 12, 13, 15, 14, 8, 9, 11, 10]

Parameters **L** (*int*) – Square root of the modulation cardinality (must be an integer).

Returns **indexes** – indexes that should be applied to the constellation created by *_createConstellation* in order to correspond to Gray mapping

Return type np.ndarray

static **_createConstellation** (*M: int*) → *numpy.ndarray*

Generates the Constellation for the (SQUARE) M-QAM modulation scheme.

Parameters **M** (*int*) – The modulation cardinality

Returns **symbols** – The QAM constellation with the desired cardinality.

Return type np.ndarray

calcTheoreticalBER (SNR: *NumberOrArray*) → *NumberOrArray*

Calculates the theoretical (approximation) bit error rate for the QAM scheme.

Parameters SNR (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns BER – The theoretical bit error rate.

Return type float | np.ndarray

calcTheoreticalSER (SNR: *NumberOrArray*) → *NumberOrArray*

Calculates the theoretical (approximation) symbol error rate for the QAM scheme.

Parameters SNR (*float* | *np.ndarray*) – Signal-to-noise-value (in dB).

Returns SER – The theoretical symbol error rate.

Return type float | np.ndarray

class pyphysim.modulators.fundamental.QPSK

Bases: *pyphysim.modulators.fundamental.PSK*

QPSK Class

pyphysim.modulators.ofdm module

Module implementing OFDM modulation and demodulation.

class pyphysim.modulators.ofdm.OFDM (*fft_size: int, cp_size: int, num_used_subcarriers: Optional[int] = None*)

Bases: *object*

OFDM class.

_add_CP (*input_data: numpy.ndarray*) → *numpy.ndarray*

Add the Cyclic prefix to the input data.

Parameters *input_data* (*np.ndarray*) – OFDM modulated data (after the IFFT). This must be a 2D numpy array with shape (Number of OFDM symbols, IFFT size).

Returns *output* – The *input_data* with the cyclic prefix added. The shape of the output is (Number of OFDM symbols, IFFT size + CP Size).

Return type np.ndarray

_calc_zeropad (*input_data_size: int*) → *Tuple[int, int]*

Calculates the number of zeros that must be added to the input data to make it a multiple of the OFDM size.

The number of zeros that must be added to the input data is returned along with the number of OFDM symbols that will be generated.

Parameters *input_data_size* (*int*) – Size the the data that will be modulated by the OFDM object.

Returns (*zeropad, num_ofdm_symbols*) – A tuple with zeropad and num_ofdm_symbols. Zeropad is the number of zeros added to the input data to make the total number of elements a multiple of the number of used subcarriers. Num_ofdm_symbols is the number of OFDM symbols required to transmit *input_data_size* symbols.

Return type *tuple[int,int]*

`_calculate_power_scale()` → `float`

Calculate the power scale that needs to be applied in the modulator and removed in the demodulate methods.

The power is applied in the modulator method so that the total power of the OFDM samples is similar to the total power of the symbols modulated by OFDM.

Note that this total power is shared among useful samples and the cyclic prefix in one OFDM symbol. Therefore, the larger the cyclic prefix size the lower is this power scale to account energy loss due to sending the cyclic prefix.

Returns `power_scale` – The calculated power scale. You should take the square root of this before multiplying by the samples.

Return type `float`

`_get_subcarrier_numbers()` → `numpy.ndarray`

Get the indexes of all subcarriers, including the negative, the DC and the positive subcarriers.

Note that these indexes are not suitable for indexing in python. They are the actual indexes of the subcarriers in an OFDM symbol. For instance, an OFDM symbol with 16 subcarriers will have indexes from -8 to 7. However, due to the way the fft is implemented in numpy the indexes here are actually from 0 to 7 followed by -8 to -1.

Returns Numbers of all subcarriers, including the negative, the DC and the positive subcarriers

Return type `np.ndarray`

Examples

```
>> ofdm_obj = OFDM(16, 4, 16) >> ofdm_obj._get_subcarrier_numbers() array([ 0, 1, 2, 3, 4, 5, 6, 7, -8, -7, -6, -5, -4, -3, -2, -1])
```

`_get_used_subcarrier_numbers()` → `numpy.ndarray`

Get the subcarrier indexes of the actually used subcarriers.

Note that these indexes are not suitable for indexing in python. They are the actual indexes of the subcarriers in an OFDM symbol. See the documentation of the `_get_subcarrier_numbers` function.

Returns Number of the actually used subcarriers.

Return type `np.ndarray`

Examples

```
>> ofdm_obj = OFDM(16, 4, 10) >> ofdm_obj._get_used_subcarrier_numbers() array([ 1, 2, 3, 4, 5, -5, -4, -3, -2, -1]) >> ofdm_obj = OFDM(16, 4, 14) >> ofdm_obj._get_used_subcarrier_numbers() array([ 1, 2, 3, 4, 5, 6, 7, -7, -6, -5, -4, -3, -2, -1])
```

`_prepare_decoded_signal(decoded_signal: numpy.ndarray)` → `numpy.ndarray`

Prepare the decoded signal that was processed by the FFT in the demodulate function.

This is equivalent of reversing the indexing that was done by the `_prepare_input_signal` method.

Parameters `decoded_signal` (`np.ndarray`) – Signal that was decoded by the FFT in the OFDM demodulate method.

Returns `demodulated_samples` – Demodulated samples of the symbols that were modulated by the OFDM object (for instance the PSK or M-QAM symbols passed to OFDM).

Return type `np.ndarray`

Notes

This method should be called AFTER the Cyclic Prefix was removed and the FFT was performed.

Also, because the number of zeropad was not saved, then `_prepare_decoded_signal` has no way to remove them.

See also:

`_prepare_input_signal()`

`_prepare_input_signal` (*input_signal: `numpy.ndarray`*) → `numpy.ndarray`

Prepare the input signal to be passed to the IFFT in the modulate function.

The input signal must be prepared before it is passed to the IFFT in the OFDM modulate function.

- First, zeros must be added so that the input signal size is multiple of the number of used subcarriers.
- After that the input signal must be allocated to subcarriers in the center of the spectrum (except for the DC component). That is, zeros will be allocated to the lower and higher subcarriers such that only `num_used_subcarriers` are used from `fft_size` subcarriers.

This preparation is performed by the `_prepare_input_signal` function.

Parameters `input_signal` (*`np.ndarray`*) – Input signal that must be modulated by the OFDM modulate function.

Returns `input_ifft` – Signal suitable to be passed to the IFFT function to actually perform the OFDM modulation.

Return type `np.ndarray`

See also:

`_prepare_decoded_signal()`

`_remove_CP` (*received_data: `numpy.ndarray`*) → `numpy.ndarray`

Remove the Cyclic prefix of the received data.

Parameters `received_data` (*`np.ndarray`*) – Data that must be demodulated by the OFDM object.

Returns `output` – Received data without the Cyclic prefix.

Return type `np.ndarray`

Notes

The `_remove_CP` method will also change the shape so that it is suitable to be passed to the FFT function.

`demodulate` (*received_signal: `numpy.ndarray`*) → `numpy.ndarray`

Perform the OFDM demodulation of the received_signal.

Parameters `received_signal` (*`np.ndarray`*) – An array with the samples of the received OFDM symbols.

Returns `demodulated_data` – Demodulated symbols.

Return type `np.ndarray`

`get_used_subcarrier_indexes` () → `numpy.ndarray`

Get the subcarrier indexes of the subcarriers actually used in a way suitable for python indexing (going from 0 to `fft_size-1`).

Returns indexes – Subcarrier indexes of the subcarriers actually used in a way suitable for python indexing.

Return type np.ndarray

Notes

This is the function actually used in the modulate function.

Examples

Consider the example below where we have 16 subcarriers and only 10 subcarriers are used. The lower and higher subcarrier as well as the DC subcarrier will not be used. The index of the used subcarriers should go then from 11 to 15 (5 subcarriers), skip subcarrier 0, and then go from 1 to 5 (the other 5 subcarriers).

```
>>> ofdm_obj = OFDM(16, 4, 10)
>>> ofdm_obj.get_used_subcarrier_indexes()
array([11, 12, 13, 14, 15, 1, 2, 3, 4, 5])
>>> ofdm_obj = OFDM(16, 4, 14)
>>> ofdm_obj.get_used_subcarrier_indexes()
array([ 9, 10, 11, 12, 13, 14, 15, 1, 2, 3, 4, 5, 6, 7])
```

modulate (*input_signal*: *numpy.ndarray*) → *numpy.ndarray*

Perform the OFDM modulation of the *input_signal*.

Parameters *input_signal* (*np.ndarray*) – Input signal that must be modulated by the OFDM modulate function.

Returns *output* – An array with the samples of the modulated OFDM symbols.

Return type np.ndarray

set_parameters (*fft_size*: *int*, *cp_size*: *int*, *num_used_subcarriers*: *Optional[int] = None*) → *None*

Set the OFDM parameters.

Parameters

- **fft_size** (*int*) – Size of the FFT and IFFT used by the OFDM class.
- **cp_size** (*int*) – Size of the cyclic prefix (in samples).
- **num_used_subcarriers** (*int*, *optional*) – Number of used subcarriers. Must be greater than or equal to 2 and lower than or equal to *fft_size*. If not provided, *fft_size* will be used

Raises *ValueError* – If the any of the parameters are invalid.

class pyphysim.modulators.ofdm.**OfdmOneTapEqualizer** (*ofdm_obj*: *pyphysim.modulators.ofdm.OFDM*)

Bases: *object*

The *OfdmOneTapEqualizer* class performs the one-tap equalization often required in OFDM transmissions to compensate the effect of the channel at each subcarrier.

Parameters *ofdm_obj* (*OFDM*) – The OFDM object used to modulate/demodulate the data.

_equalize_data (*data_reshaped*: *numpy.ndarray*, *mean_freq_response*: *numpy.ndarray*) → *numpy.ndarray*

Perform the one-tap equalization and return *data* after the channel compensation.

Parameters

- **data_reshaped** (*np.ndarray*) – The data to be equalized. It must be a 2D numpy array, where different rows correspond to different OFDM symbols and the different columns correspond to the USED subcarriers. Dimension: *num OFDM symbols x num Used subcarriers*
- **mean_freq_response** (*np.ndarray*) – The frequency response for each OFDM symbol. Dimension: *num OFDM symbols x FFT size*

Returns The received *data* after the one-tap equalization to compensate the channel effect. Dimension: *num OFDM symbols x num Used subcarriers*

Return type *np.ndarray*

equalize_data (*data*: *numpy.ndarray*, *impulse_response*: *py-physim.channels.fading.TdlImpulseResponse*) → *numpy.ndarray*

Perform the one-tap equalization and return *data* after the channel compensation.

Parameters

- **data** (*np.ndarray*) – The data to be equalized.
- **impulse_response** (*fading.TdlImpulseResponse*) – The impulse response of the channel.

Returns The received *data* after the one-tap equalization to compensate the channel effect.

Return type *np.ndarray*

Module contents

Package containing modulators.

pyphysim.pointprocess package

Submodules

pyphysim.pointprocess.pointprocess module

`pyphysim.pointprocess.pointprocess.generate_random_points_in_circle` (*num_points*: *int*, *max_radius*: *float*, *min_radius*: *float* = 0.0) → *numpy.ndarray*

Generate *numPoints* points uniformly inside a circle of radius *max_radius* and outside a circle with radius *min_radius*

The circle center is at the origin.

Parameters

- **num_points** – The desired number of points
- **max_radius** – The circle radius
- **min_radius** – The minimum radius

Returns The random points inside the circle.

Return type np.ndarray

```
pyphysim.pointprocess.pointprocess.generate_random_points_in_rectangle(num_points:
                                                                    int,
                                                                    width:
                                                                    float,
                                                                    height:
                                                                    float)
```

Generate *num_points* points uniformly inside a rectangle.

The rectangle center is at the origin.

Parameters

- **num_points** – The desired number of points
- **width** – The rectangle width
- **height** – The rectangle height

Returns The random points inside the circle.

Return type np.ndarray

Module contents

pyphysim.progressbar package

Submodules

pyphysim.progressbar.progressbar module

Implement classes to represent the progress of a task.

Use the `ProgressbarText` class for tasks that do not use multiprocessing, and the `ProgressbarMultiProcessServer` class for tasks using multiprocessing.

Basically, the task code must call the “progress” function to update the progress bar and pass a number equivalent to the increment in the progress since the last call. The progressbar must know the maximum value equivalent to all the progress, which is passed during object creator for `ProgressbarText` class.

The `ProgressbarMultiProcessServer` is similar to `ProgressbarText` class, accounts for the progress of multiple processes. For each process you need to call the `register_client_and_get_proxy_progressbar` to get a proxy progressbar, where the maximum value equivalent to all the progress that will be performed by that process is passed in this proxy creation. Each process then calls the `progress` method of the proxy progressbar.

Note that there is also a `DummyProgressbar` whose progress function does nothing. This is useful when you want to give the user a choice to show or not the progressbar such that the task code can always call the `progress` method and you only change the progressbar object.

```
class pyphysim.progressbar.progressbar.DummyProgressbar(*args: Any, **kwargs: Any)
```

Bases: `object`

Dummy progress bar that don't really do anything.

The idea is that it can be used in place of the `ProgressbarText` class, but without actually doing anything.

See also:

*ProgressbarText***progress** (*count: int*) → *None*

This *progress* method has the same signature from the one in the *ProgressbarText* class.

Nothing happens when this method is called.

Parameters *count* (*int*) – Ignored

class pyphysim.progressbar.progressbar.**ProgressBarBase** (*finalcount: int*)

Bases: *object*

Base class for all *ProgressBar* classes.

Parameters *finalcount* (*int*) – The total amount that corresponds to 100%. Each time the *progress* method is called with a number that number is added with the current amount in the progressbar. When the amount becomes equal to *finalcount* the bar will be 100% complete.

Notes

Derived classes should implement *_update_iteration()* and *_display_current_progress()*. Optionally derived class might also implement *_perform_initialization()* and *_perform_finalizations()*

_count_to_percent (*count: int*) → *float*

Convert a given count into the equivalent percentage.

Parameters *count* (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of *self.finalcount*

Returns *percentage* – The percentage that *count* is of *self.finalcount* (between 0 and 100)

Return type *float*

_display_current_progress () → *None*

Refresh the progress representation.

This method should be defined in a subclass.

_perform_finalizations () → *None*

Perform any finalization (cleanings) after the progressbar stops.

This method should be implemented in sub-classes if any finalization code should be run.

_perform_initialization () → *None*

Perform any initializations for the progressbar.

This method should be implemented in sub-classes if any initialization code should be run.

_update_iteration (*count: int*) → *None*

Update the progressbar according with the new *count*.

Parameters *count* (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of *self.finalcount*

property *elapsed_time*

Get method for the *elapsed_time* property.

Returns The elapsed time.

Return type *str*

final progress (*count: int*) → *None*

Updates the current progress.

Calling this function will update the the current progress.

Parameters *count* (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of *self.finalcount*

Notes

How the progressbar is actually represented depends on the subclass. In the subclasses implement the *_update_iteration* method to update the current representation of the progressbar and the *_update_progress_display* to actually display the current progress.

final start () → *None*

Start the progressbar.

This method should be called just before the progressbar is used for the first time. Among possible other things, it will store the current time so that the elapsed time can be tracked.

If is automatically called in the *progress* method, if not called before.

final stop () → *None*

Stop the progressbar.

This method is automatically called in the *progress* method when the progress reaches 100%. If manually called, any subsequent call to the *progress* method will be ignored.

class *pyphysim.progressbar.progressbar.ProgressBarIPython* (*finalcount: int*,
side_message: Optional[str] = None)

Bases: *pyphysim.progressbar.progressbar.ProgressBarBase*

Progressbar for IPython notebooks.

The progressbar will be rendered using IPython widgets.

_display_current_progress () → *None*

Refresh the progress representation.

_perform_initialization () → *None*

Perform any initializations for the progressbar.

This method should be implemented in sub-classes if any initialization code should be run.

_update_iteration (*count: int*) → *None*

Update the *self.prog_bar* member variable according with the new *count*.

Parameters *count* (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of *self.finalcount*

class *pyphysim.progressbar.progressbar.ProgressBarDistributedClientBase* (*client_id: int*,
finalcount: int)

Bases: *pyphysim.progressbar.progressbar.ProgressBarBase*

Proxy progressbar that behaves like a *ProgressbarText* object, but is actually updating a shared (with other clients) progressbar.

The basic idea is that this proxy progressbar has the “progress” method similar to the standard `ProgressbarText` class. However, when this method is called it will update a value that will be read by a “server progressbar” object which is responsible to actually show the current progress.

Parameters `client_id` (*ClientID*) – The client ID.

`_display_current_progress()` → `None`

Refresh the progress representation.

This method should be defined in a subclass.

`_update_iteration(count: int)` → `None`

Update the progressbar according with the new *count*.

Parameters `count` (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of `self.finalcount`

```
class pyphysim.progressbar.progressbar.ProgressbarDistributedServerBase (progresschar:
                                                                    str
                                                                    =
                                                                    '*',
                                                                    mes-
                                                                    sage:
                                                                    str
                                                                    =
                                                                    ",
                                                                    sleep_time:
                                                                    float
                                                                    =
                                                                    1.0,
                                                                    file-
                                                                    name:
                                                                    Op-
                                                                    tional[str]
                                                                    =
                                                                    None,
                                                                    style='text2')
```

Bases: `object`

Base class for progressbars for distributed computations.

In order to track the progress of distributed computations two classes are required, one that acts as a central point and is responsible to actually show the progress (the server), and other class that acts as a proxy (the client) and is responsible to sending the current progress to the server. There will be one object of the “server class” and one or more objects of the “client class”, each one tracking the progress of one of the distributed computations.

This class is a base class for the “server part”, while the `ProgressbarDistributedClientBase` class is a base class for the “client part”.

For a full implementation, see the `ProgressbarMultiProcessServer` and `ProgressbarMultiProcessClient` classes.

Parameters

- **progresschar** (*str*) – Character used in the progressbar.
- **message** (*str*) – Message written in the progressbar.
- **sleep_time** (*float*) – Time between progressbar updates (in seconds).

- **filename** (*str*) – If filename is None (default) then progress will be output to sys.stdout. If it is not None then the progress will be output to a file with name *filename*. This is usually useful for debugging and testing purposes.
- **style** (*str*) – The progressbar style. It controls which progressbar is used to display progress. It can be either 'text1', 'text2', 'text3', or 'ipython'

`__ProgressbarDistributedServerBase__create_inner_progressbar` (*output*)

`__register_client` (*total_count: int*) → *int*

Register a new “client” for the progressbar and return its *client_id*.

These returned values must be passed to the corresponding proxy progressbar.

Parameters **total_count** (*int*) – Total count that will be equivalent to 100% progress for the function.

Returns **client_id** – The *client_id*. The function whose process is tracked by the Progressbar-MultiProcessServer must update the element *client_id* with the current count.

Return type ClientID

`__update_client_data_list` () → *None*

This method process the communication between the client and the server.

It should gather the information sent by the clients (proxy progressbars) and update the member variable *self._client_data_list* accordingly, which will then be automatically represented in the progressbar.

`__update_progress` (*filename: Optional[str] = None, start_delay: float = 0.0*) → *None*

Collects the progress from each registered proxy progressbar and updates the actual visible progressbar.

Parameters

- **filename** (*str*) – Name of a file where the data will be written to. If this is None then all progress will be printed in the standard output (default)
- **start_delay** (*float, optional*) – Delay in seconds before starting the progressbar. During this time it is still possible to register new clients and the progressbar will only be shown after this delay..

`register_client_and_get_proxy_progressbar` (*total_count: int*) → *py-physim.progressbar.progressbar.ProgressbarDistributedClientBase*

Register a new “client” for the progressbar and returns a new proxy progressbar that the client can use to update its progress by calling the *progress* method of this proxy progressbar.

Parameters **total_count** (*int*) – Total count that will be equivalent to 100% for function.

Returns **obj** – The proxy progressbar.

Return type Object of a class derived from ProgressbarDistributedClientBase

`start_updater` (*start_delay: float = 0.0*) → *None*

Start the process that updates the progressbar.

Parameters **start_delay** (*float*) – Delay in seconds before starting the progressbar. During this time it is still possible to register new clients and the progressbar will only be shown after this delay..

Notes

If this method is called multiple times then the `stop_updater` method must be called the same number of times for the updater process to actually stop.

stop_updater (*timeout: Optional[float] = None*) → *None*

Stop the process updating the progressbar.

You should always call this function in your main process (the same that created the progressbar) after joining all the processes that update the progressbar. This guarantees that the progressbar updated any pending change and exited clearly.

Parameters *timeout* (*float*) – The timeout to join for the process to stop.

Notes

If the `start_updater` was called multiple times the process will only be stopped when `stop_updater` is called the same number of times.

property total_final_count

Get method for the `total_final_count` property.

Returns The final count.

Return type *int*

```
class pyphysim.progressbar.progressbar.ProgressbarMultiProcessClient (client_id:
                                                                    int,
                                                                    client_data_list:
                                                                    List[Any],
                                                                    final-
                                                                    count:
                                                                    int)
```

Bases: `pyphysim.progressbar.progressbar.ProgressbarDistributedClientBase`

Proxy progressbar that behaves like a `ProgressbarText` object, but is actually updating a `ProgressbarMultiProcessServer` progressbar.

The basic idea is that this proxy progressbar has the “progress” method similar to the standard `ProgressbarText` class. However, when this method is called it will update a value that will be read by a `ProgressbarMultiProcessServer` object instead.

Parameters

- **client_id** (*ClientID*) – The client ID
- **client_data_list** (*list*) – The client data list

_update_iteration (*count: int*) → *None*

Updates the proxy progress bar.

Parameters *count* (*int*) – The new amount of progress.

```
class pyphysim.progressbar.progressbar.ProgressBarMultiProcessServer (progresschar:
                                                                    str =
                                                                    '*',
                                                                    mes-
                                                                    sage:
                                                                    str = "",
                                                                    sleep_time:
                                                                    float
                                                                    = 1.0,
                                                                    file-
                                                                    name:
                                                                    Op-
                                                                    tional[str]
                                                                    =
                                                                    None,
                                                                    style:
                                                                    str =
                                                                    'text2')
```

Bases: `pyphysim.progressbar.progressbar.ProgressBarDistributedServerBase`

Class that prints a representation of the current progress of multiple process as text.

While the `ProgressBarText` class only tracks the progress of a single process, the `ProgressBarMultiProcessServer` class can track the joint progress of multiple processes. This may be used, for instance, when you parallelize some task using the multiprocessing module.

Using the `ProgressBarMultiProcessServer` class requires a little more work than using the `ProgressBarText` class, as it is described in the following:

1. First you create an object of the `ProgressBarMultiProcessServer` class as usual. However, differently from the `ProgressBarText` class you don't pass the `finalcount` value to the progressbar yet.
2. After that, for each process to be tracked, call the `register_client_and_get_proxy_progressbar()` method passing the number equivalent to full progress for **that process**. This function returns a “proxy progressbar” that behaves like a regular `ProgressBarText`. Pass that proxy progressbar as an argument to that process so that it can call its “progress” method. Each process that calls the “progress” method of the received proxy progressbar will actually update the progress of the main `ProgressBarMultiProcessServer` object.
3. Start all the processes and call the `start_updater` method of `ProgressBarMultiProcessServer` object so that the bar is updated by the different processes.
4. After joining all the process (all work is finished) call the `stop_updater` method of the `ProgressBarMultiProcessServer` object.

Parameters

- **progresschar** (*str*) – Character used in the progressbar.
- **message** (*str*) – Message written in the progressbar.
- **sleep_time** (*float*) – Time between progressbar updates (in seconds).
- **filename** (*str*) – If filename is None (default) then progress will be output to sys.stdout. If it is not None then the progress will be output to a file with name *filename*. This is usually useful for debugging and testing purposes.

Examples

```
import multiprocessing
# Create a ProgressbarMultiProcessServer object
pb = ProgressbarMultiProcessServer(message="some message")
# Creates a proxy progressbar for one process passing the value
# corresponding to 100% progress for the first process
proxybar1 = pb.register_client_and_get_proxy_progressbar(60)
# Creates a proxy progressbar for another process
proxybar2 = pb.register_client_and_get_proxy_progressbar(80)
# Create the first process passing the first proxy progressbar as
# an argument
p1 = multiprocessing.Process(target=some_function, args=[proxybar1])
# Creates another process
p2 = multiprocessing.Process(target=some_function, args=[proxybar2])
# Start both processes
p1.start()
p2.start()
# Call the start_updater method of the ProgressbarMultiProcessServer
pb.start_updater()
# Join the process and then call the stop_updater method of the
# ProgressbarMultiProcessServer
p1.join()
p2.join()
pb.stop_updater()
```

`_update_client_data_list()` → `None`

This method process the communication between the client and the server.

`register_client_and_get_proxy_progressbar` (*total_count*: `int`) → `py-`
`physim.progressbar.progressbar.ProgressbarMultiProcessClient`

Register a new “client” for the progressbar and returns a new proxy progressbar that the client can use to update its progress by calling the *progress* method of this proxy progressbar.

The function whose process is tracked by the ProgressbarMultiProcessServer must must call the *progress* method of the returned ProgressbarMultiProcessClient object with the current count. This is a little less intrusive regarding the tracked function.

Parameters *total_count* (`int`) – Total count that will be equivalent to 100% for function.

Returns *obj* – The proxy progressbar.

Return type `ProgressbarMultiProcessClient`

`class` `pyphysim.progressbar.progressbar.ProgressbarText` (*finalcount*: `int`, *progress-*
char: `str` = `'*`, *message*:
`str` = `"`, *output*: `Any`
= `<_io.TextIOWrapper`
`name='<stdout>' mode='w'`
`encoding='utf-8'>`)

Bases: `pyphysim.progressbar.progressbar.ProgressbarTextBase`

Class that prints a representation of the current progress as text.

You can set the final count for the progressbar, the character that will be printed to represent progress and a small message indicating what the progress is related to.

In order to use this class, create an object outside a loop and inside the loop call the *progress* function with the number corresponding to the progress (between 0 and finalcount). Each time the *progress* function is called a

number of characters will be printed to show the progress. Note that the number of printed characters correspond is equivalent to the progress minus what was already printed.

DummyProgressbar

Examples

```
>> pb = ProgressbarText(100, 'o', "Hello Simulation") >> pb.start()
_____1_____ Hello Simulation
```

1 2 3 4 5 6 7 8 9 0

[illegible]

```
__ProgressBarText__get_initialization_bartitle() → str
```

Get the progressbar title.

The title is the first line of the progressbar initialization message.

The bar title is something like the line below

_____ % Progress _____1

when there is no message.

Returns The bar title.

Return type `str`

Notes

This method is only a helper method called in the `_perform_initialization` method.

```
__ProgressBarText__ get_initialization_markers() → Tuple[str, str]
```

The initialization markers ‘mark’ the current progress in the progressbar that will appear below it.

Returns A tuple containing the ‘two lines’ with the progress markers. That is, (marker_line1, marker_line2)

Return type Tuple[[str](#), [str](#)]

Notes

This method is only a helper method called in the `_perform_initialization` method.

```
_perform_initialization() → None
```

Perform any initializations for the progressbar.

This method should be implemented in sub-classes if any initialization code should be run.

```
_update_iteration (count: int) → None
```

Update the progressbar according with the new *count*.

Parameters `count` (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of `self.finalcount`

```
class pyphysim.progressbar.progressbar.ProgressBarText2 (finalcount: int, progress-
char: str = '*', message:
str = "", output: Any
= <_io.TextIOWrapper
name='<stdout>'
mode='w' encoding='utf-
8'>)
```

Bases: `pyphysim.progressbar.progressbar.ProgressBarTextBase`

Class that prints a representation of the current progress as text.

You can set the final count for the progressbar, the character that will be printed to represent progress and a small message indicating what the progress is related to.

In order to use this class, create an object outside a loop and inside the loop call the *progress* function with the number corresponding to the progress (between 0 and finalcount). Each time the *progress* function is called a number of characters will be printed to show the progress. Note that the number of printed characters correspond is equivalent to the progress minus what was already printed.

Parameters

- **finalcount** (*int*) – The total amount that corresponds to 100%. Each time the progress method is called with a number that number is added with the current amount in the progressbar. When the amount becomes equal to *finalcount* the bar will be 100% complete.
- **progresschar** (*str*, optional (default to '*')) – The character used to represent progress.
- **message** (*str*, optional) – A message to be shown in the right of the progressbar. If this message contains "{elapsed_time}" it will be replaced by the elapsed time.
- **output** (*File like object*) – Object with a 'write' method, which controls where the progress-bar will be printed. By default sys.stdout is used, which means that the progress will be printed in the standard output.

_update_iteration (*count: int*) → *None*

Update the self.prog_bar member variable according with the new *count*.

Parameters *count* (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of self.finalcount

```
class pyphysim.progressbar.progressbar.ProgressBarText3 (finalcount: int, progress-
char: str = '*', message:
str = "", output: Any
= <_io.TextIOWrapper
name='<stdout>'
mode='w' encoding='utf-
8'>)
```

Bases: `pyphysim.progressbar.progressbar.ProgressBarTextBase`

Class that prints a representation of the current progress as text.

You can set the final count for the progressbar, the character that will be printed to represent progress and a small message indicating what the progress is related to.

In order to use this class, create an object outside a loop and inside the loop call the *progress* function with the number corresponding to the progress (between 0 and finalcount). Each time the *progress* function is called a number of characters will be printed to show the progress. Note that the number of printed characters correspond is equivalent to the progress minus what was already printed.

Parameters

finalcount [int] The total amount that corresponds to 100%. Each time the progress method is called with a number that number is added with the current amount in the progressbar. When the amount becomes equal to *finalcount* the bar will be 100% complete.

progresschar [str, optional (default to '*')] The character used to represent progress.

message [str, optional] A message to be shown in the progressbar.

output [File like object] Object with a 'write' method, which controls where the progress-bar will be printed. By default sys.stdout is used, which means that the progress will be printed in the standard output.

`_update_iteration` (*count: int*) → None

Update the self.prog_bar member variable according with the new *count*.

Parameters **count** (*int*) – The current count to be represented in the progressbar. The progressbar represents this count as a percent value of self.finalcount

```
class pyphysim.progressbar.progressbar.ProgressBarTextBase (finalcount: int, progresschar: str = '*', message: str = '', output: Any = <_io.TextIOWrapper name='<stdout>' mode='w' encoding='utf-8'>)
```

Bases: `pyphysim.progressbar.progressbar.ProgressBarBase`

Base class for Text progressbars.

Parameters

- **finalcount** (*int*) – The total amount that corresponds to 100%. Each time the progress method is called with a number that number is added with the current amount in the progressbar. When the amount becomes equal to *finalcount* the bar will be 100% complete.
- **progresschar** (*str*, *optional*) – The character used to represent progress.
- **message** (*str*, *optional*) – A message to be shown in the top of the progressbar.
- **output** (*File like object*) – Object with a 'write' method, which controls where the progress-bar will be printed. By default sys.stdout is used, which means that the progress will be printed in the standard output.

Notes

Derived classes must implement at least `_update_iteration` and this method should update the *prog_bar* member variable with the text representation of the progress.

`_display_current_progress` () → None

Refresh the progress representation.

All text progressbars should implement the `_update_iteration` to update the *prog_bar* member variable with the text representation of the progressbar.

This method is responsible to sending this text representation to the output.

`_get_percentage_representation` (*percent: float*, *central_message: str = '{percent}%', left_side: str = '[', right_side: str = ']'*) → str

Get the percent representation as a string suitable to the text progressbar.

Parameters

- **percent** (*float*) – The percentage to be represented.
- **central_message** (*str*) – A message that will be in the middle of the percentage bar. If there is the label '{percent}' in the central_message it will be replaced by the percentage. If there is the label '{elapsed_time}' in the central_message it will be replaced by the elapsed time. Note that this message should be very small, since it hides the progresschars.
- **left_side** (*str*) – The left side of the bar.
- **right_side** (*str*) – The right side of the bar.

Returns **representation** – A string with the representation of the percentage.

Return type *str*

`_maybe_delete_output_file()` → *None*

Delete the output file (if there is any) when `delete_progress_file_after_completion` is set to `True`.

`_perform_finalizations()` → *None*

Perform any finalization (cleanings) after the progressbar stops.

property **width**

Get method for the width property.

```
class pyphysim.progressbar.progressbar.ProgressBarZMQClient (client_id: int, ip: str,
                                                            port: int, finalcount:
                                                            int)
```

Bases: *pyphysim.progressbar.progressbar.ProgressBarDistributedClientBase*

Proxy progressbar that behaves like a `ProgressBarText` object, but is actually updating a `ProgressBarZMQServer` progressbar.

The basic idea is that this proxy progressbar has the “progress” method similar to the standard `ProgressBarText` class. However, when this method is called it will update a value that will be read by a `ProgressBarZMQServer` object instead.

Parameters

- **client_id** (*ClientID*) – The client ID.
- **ip** (*IPAddress*) – A string representing the IP address of the server.
- **port** (*PortNumber*) – The port number used by the server.

`_perform_initialization()` → *None*

Creates the “push socket”, connects it to the socket of the main progressbar and then updates the progress.

This function will be called only in the first time the “progress” method is called. Subsequent calls to “progress” will actually calls the “_progress” method.

Parameters **count** (*int*) – The new amount of progress.

`_update_iteration` (*count: int*) → *None*

Updates the proxy progress bar.

Parameters **count** (*int*) – The new amount of progress.

```
class pyphysim.progressbar.progressbar.ProgressBarZMQServer (progresschar: str =
                                                            '*', message: str =
                                                            ", sleep_time: float
                                                            = 1.0, filename: Op-
                                                            tional[str] = None,
                                                            ip: str = 'localhost',
                                                            port: int = 7396,
                                                            style: str = 'text2')
```

Bases: `pyphysim.progressbar.progressbar.ProgressBarDistributedServerBase`

Distributed “server” progressbar using ZMQ sockets.

In order to track the progress of distributed computations two classes are required, one that acts as a central point and is responsible to actually show the progress (the server), and other class that acts as a proxy (the client) and is responsible to sending the current progress to the server. There will be one object of the “server class” and one or more objects of the “client class”, each one tracking the progress of one of the distributed computations.

This class acts like the server. It creates a ZMQ socket which expects (string) messages in the form “client_id:current_progress”, where the client_id is the ID of one client progressbar previously registered with the register_client_and_get_proxy_progressbar method while the current_progress is a “number” with the current progress of that client.

Note that the client proxybar for this class is implemented in the ProgressbarZMQClient class.

Parameters

- **progresschar** (*str*) – Character used in the progressbar.
- **message** (*str*) – Message written in the progressbar.
- **sleep_time** (*float*) – Time between progressbar updates (in seconds).
- **filename** (*str*) – If filename is None (default) then progress will be output to sys.stdout. If it is not None then the progress will be output to a file with name *filename*. This is usually useful for debugging and testing purposes.
- **ip** (*IPAddress*) – An string representing the address of the server socket. Ex: ‘192.168.0.117’, ‘localhost’, etc.
- **port** (*PortNumber*) – The port to bind the socket.

_parse_progress_message (*message: str*) → *None*

Parse the message sent from the client proxy progressbars.

The messages sent from the proxy progressbars are in the form ‘client_id:current_count’. We need to set the element of index “client_id” in self._client_data_list to the value of “current_count”. This method will simply parse the message and perform this operation.

Parameters message (*str*) – A string in the form ‘client_id:current_count’.

_update_client_data_list () → *None*

This method process the communication between the client and the server.

This method will read the received messages in the socket which were sent by the clients (ProgressbarZMQClient objects) and update self._client_data_list variable accordingly. The messages are in the form “client_id:current_progress”, which is parsed by the _parse_progress_message method.

Notes

This method is called inside a loop in the _update_progress method.

_update_progress (*filename: Optional[str] = None, start_delay: float = 0.0*) → *None*

Collects the progress from each registered proxy progressbar and updates the actual visible progressbar.

Parameters

- **filename** (*str*) – Name of a file where the data will be written to. If this is None then all progress will be printed in the standard output (default)

- **start_delay** (*float*) – Delay in seconds before starting the progressbar. During this time it is still possible to register new clients and the progressbar will only be shown after this delay.

Notes

We re-implement it here only to create the ZMQ socket. After that we call the base class implementation of `_update_progress` method. Note that the `_update_progress` method in the base class calls the `_update_client_data_list` and we indeed re-implement this method in this class and use the socket created here in that implementation.

property ip

Get method for the ip property.

Returns The string representing the address of the server socket.

Return type `str`

property num_clients

Number of registered clients

property port

Get method for the port property.

Returns The port used.

Return type `int`

register_client_and_get_proxy_progressbar (*total_count*: `int`) → *py-*
physim.progressbar.progressbar.ProgressBarZMQClient

Register a new client progressbar and return a proxy to it.

Parameters **total_count** (`int`) – The total count for the client we are registering.

Returns The proxy progressbar.

Return type *ProgressBarZMQClient*

Module contents

pyphysim.reference_signals package

Submodules

pyphysim.reference_signals.channel_estimation module

Module with channel estimation implementations based on the reference signals in this package.

class `pyphysim.reference_signals.channel_estimation.CazacBasedChannelEstimator` (*ue_ref_seq*:
Union[pyphysim
py-
physim.reference
numpy.ndarray],
size_multiplier:
int
=
2)

Bases: `object`

Estimated the (uplink) channel based on CAZAC (Constant Amplitude Zero AutoCorrelation) reference sequences sent by one user (either SRS or DMRS).

The estimation is performed according to the paper [Bertrand2011], where the received signal in the FREQUENCY DOMAIN is used by the estimator.

Note that for SRS sequences usually a comb pattern is employed such that only half of the subcarriers is used to send pilot symbols. Therefore, an FFT in the during the estimation will effectively interpolate for the other subcarriers. This is controlled by the *size_multiplier* argument (default is 2 to accommodate comb pattern). If all subcarriers are used to send pilot symbols then set *size_multiplier* to 1.

Parameters

- **ue_ref_seq** (*SrsUeSequence* | *DmrsUeSequence* | *np.ndarray*) – The reference signal sequence.
- **size_multiplier** (*int*, *optional*) – Multiplication factor for the FFT to get the actual channel size. When using the comb pattern for SRS this should be 2 (default value), but for DMRS, which does not employ the comb pattern, this should be set to 1.

Notes

estimate_channel_freq_domain (*received_signal*: *numpy.ndarray*, *num_taps_to_keep*: *int*) → *numpy.ndarray*

Estimate the channel based on the received signal.

Parameters

- **received_signal** (*np.ndarray*) – The received reference signal after being transmitted through the channel (in the frequency domain). If this is a 2D numpy array the first dimensions is assumed to be “receive antennas” while the second dimension are the received sequence elements. The number of elements in the received signal (per antenna) is equal to the channel size (number of subcarriers) divided by *size_multiplier*.
- **num_taps_to_keep** (*int*) – Number of taps (in delay domain) to keep. All taps from 0 to *num_taps_to_keep*-1 will be kept and all other taps will be zeroed before applying the FFT to get the channel response in the frequency domain.

Returns freq_response – The channel frequency response. Note that for SRS sequences this will have twice as many elements as the sent SRS signal, since the SRS signal is sent every other subcarrier.

Return type *np.ndarray*

property ue_ref_seq

Get the sequence of the UE.

class *pyphysim.reference_signals.channel_estimation.CazacBasedWithOCCChannelEstimator* (*ue_ref*

py-
physim

Bases: *pyphysim.reference_signals.channel_estimation.CazacBasedChannelEstimator*

Estimated the (uplink) channel based on CAZAC (Constant Amplitude Zero AutoCorrelation) reference sequences sent by one user including the Orthogonal Cover Code (OCC).

With OCC the user will send reference signal in multiple time slots, in each slot multiplied with the respective OCC sequence element.

Parameters ue_ref_seq (*DmrsUeSequence*) – The reference signal sequence.

property cover_code

Get the cover code of the UE.

estimate_channel_freq_domain (*received_signal*: *numpy.ndarray*, *num_taps_to_keep*: *int*, *extra_dimension*: *bool = True*) → *numpy.ndarray*

Estimate the channel based on the received signal with cover codes.

Parameters

- **received_signal** (*np.ndarray*) – The received reference signal after being transmitted through the channel (in the frequency domain).

Dimension: Depend if there are multiple receive antennas and if *extra_dimension* is True or False. Let N_r be the number of receive antennas, N_e be the number of reference signal elements (reference signal size without cover code) and N_c be the cover code size. The dimension of *received_signal* must match the table below.

| / | <i>extra_dimension</i> : True | <i>extra_dimension</i> : False |
|-------------------|----------------------------------|--------------------------------|
| Single Antenna | $N_c \times N_e$ (2D) | $N_e * N_c$ (1D) |
| Multiple Antennas | $N_r \times N_c \times N_e$ (3D) | $N_r \times (N_e * N_c)$ (2D) |

- **num_taps_to_keep** (*int*) – Number of taps (in delay domain) to keep. All taps from 0 to *num_taps_to_keep*-1 will be kept and all other taps will be zeroed before applying the FFT to get the channel response in the frequency domain.
- **extra_dimension** (*bool*) – If True then there should be an extra dimension in *received_signal* corresponding to the cover code dimension. If False then the cover code is included in the dimension of the reference signal elements.

Returns *freq_response* – The channel frequency response.

Return type *np.ndarray*

pyphysim.reference_signals.dmrs module

Module with Sounding Reference Signal (SRS) related functions

class *pyphysim.reference_signals.dmrs.DmrsUeSequence* (*root_seq*: *pyphysim.reference_signals.root_sequence.RootSequence*, *n_cs*: *int*, *cover_code*: *Optional[numpy.ndarray] = None*, *normalize*: *bool = False*)

Bases: *pyphysim.reference_signals.srs.UeSequence*

DMRS sequence of a single user.

Parameters

- **root_seq** (*RootSequence*) – The DMRS root sequence of the base station the user is associated to. This should be an object of the *RootSequence* class.
- **n_cs** (*int*) – The shift index of the user. This can be an integer from 0 to 11.
- **cover_code** (*np.ndarray*, *optional*) – Cover Code used by the UE. As an example, consider the cover code *np.array([1, -1])*. In that case, if the regular DMRS sequence (without the cover code) is *seq*, then the actual DMRS sequence with cover code will be a 2D numpy array equivalent with *seq_occ[0]==seq* and *seq_occ[1]==-seq*.
- **normalize** (*bool*) – True if the reference signal should be normalized. False otherwise.

property cover_code

Return the cover code.

property size

Return the size of the reference signal sequence.

Returns **size** – The size of the user’s reference signal sequence.

Return type **int**

`pyphysim.reference_signals.dmrs.get_dmrs_seq(root_seq: numpy.ndarray, n_cs: int) → numpy.ndarray`

Get the shifted root sequence suitable as the DMRS sequence of a user.

Parameters

- **root_seq** (*np.ndarray*) – The root sequence to shift.
- **n_cs** (*int*) – The desired cyclic shift number. This should be an integer from 0 to 11, where 0 will just return the base sequence, 1 gives the first shift, and so on.

Returns The shifted root sequence.

Return type *np.ndarray*

See also:

`zadoffchu.get_shifted_root_seq()`, `srs.get_srs_seq()`

pyphysim.reference_signals.root_sequence module

Module with Sounding Reference Signal (SRS) related functions

class `pyphysim.reference_signals.root_sequence.RootSequence` (*root_index: int*,
size: Optional[int]
= None, Nzc: Optional[int] = None)

Bases: *object*

Class representing the root sequence of the reference signals.

The root sequence is generated using two possible formulas, one used for a sequence size smaller than $3M_{sc}^{RS}$ and another for sequence size equal to or greater than $3M_{sc}^{RS}$, where $3M_{sc}^{RS}$ is the number of subcarriers in a PRB (12 subcarriers).

Parameters

- **root_index** (*int*) – The SRS root sequence index.
- **size** (*int*) – The size of the extended Zadoff-Chu sequence. If None then the sequence will not be extended and will thus have a size equal to Nzc.
- **Nzc** (*int*) – The size of the Zadoff-Chu sequence (without any extension). If not provided then the largest prime number lower than or equal to *size* will be used.

property Nzc

Get the size of the Zadoff-Chu sequence (without any extension).

Returns The value of the Nzc property.

Return type **int**

static `_get_largest_prime_lower_than_number` (*seq_size: int*) → *int*

Get the largest prime number lower than *seq_size*.

Parameters `seq_size (int)` – The sequence size.

Returns The largest prime number lower than `seq_size`.

Return type `int`

conj () → `numpy.ndarray`

Return the conjugate of the root sequence as a numpy array.

Returns The conjugate of the root sequence.

Return type `np.ndarray`

conjugate () → `numpy.ndarray`

Return the conjugate of the root sequence as a numpy array.

Returns The conjugate of the root sequence.

Return type `np.ndarray`

property index

Return the SRS root sequence index.

Returns The root sequence index.

Return type `int`

n_sc_PRB = 12

seq_array () → `numpy.ndarray`

Get the extended Zadoff-Chu root sequence as a numpy array.

Returns `seq` – The extended Zadoff-Chu sequence

Return type `np.ndarray`

property size

Return the size (with extension) of the sequence.

If the sequence is not extended than `size()` will return the same as `Nzc`.

Returns `size` – The size of the extended Zadoff-Chu sequence.

Return type `int`

Examples

```
>>> seq1 = RootSequence(root_index=25, Nzc=139)
>>> seq1.size
139
>>> seq1 = RootSequence(root_index=25, Nzc=139, size=150)
>>> seq1.size
150
```

pyphysim.reference_signals.srs module

Module with Sounding Reference Signal (SRS) related functions

```
class pyphysim.reference_signals.srs.SrsUeSequence (root_seq: py-  
physim.reference_signals.root_sequence.RootSequence,  
n_cs: int, normalize: bool =  
False)
```

Bases: pyphysim.reference_signals.srs.UeSequence

SRS sequence of a single user.

Parameters

- **root_seq** (*RootSequence*) – The SRS root sequence of the base station the user is associated to. This should be an object of the RootSequence class.
- **n_cs** (*int*) – The shift index of the user. This can be an integer from 0 to 7.
- **normalize** (*bool*) – True if the reference signal should be normalized. False otherwise.

```
pyphysim.reference_signals.srs.get_srs_seq (root_seq: numpy.ndarray, n_cs: int) →  
numpy.ndarray
```

Get the shifted root sequence suitable as the SRS sequence of a user.

Parameters

- **root_seq** (*np.ndarray*) – The root sequence to shift. This is a complex numpy array.
- **n_cs** (*int*) – The desired cyclic shift number. This should be an integer from 0 to 7, where 0 will just return the base sequence, 1 gives the first shift, and so on.

Returns The shifted root sequence.

Return type np.ndarray

See also:

```
get_shifted_root_seq(), dmrs.get_dmrs_seq()
```

pyphysim.reference_signals.zadoffchu module

Module containing Zadoff-chu related functions.

```
pyphysim.reference_signals.zadoffchu.calcBaseZC (Nzc: int, u: int, q: complex = 0) →  
numpy.ndarray
```

Calculate the root sequence of Zadoff-Chu sequences.

Parameters

- **Nzc** (*int*) – The size of the root Zadoff-Chu sequence.
- **u** (*int*) – The root sequence index.
- **q** (*complex*) – Any complex number. Usually this is just zero.

Returns **a_u** – The root Zadoff-Chu sequence.

Return type np.ndarray

```
pyphysim.reference_signals.zadoffchu.get_extended_ZF (root_seq: numpy.ndarray, size:  
int) → numpy.ndarray
```

Cyclic Extend the Zadoff-Chu root sequence to have size equal to *size*.

Parameters

- **root_seq** (*np.ndarray*) – The root Zadoff-Chu sequence. This is a complex numpy array.
- **size** (*int*) – The size that the sequence should be extended to.

Returns output – The extended root sequence.

Return type *np.ndarray*

Examples

```
>>> root_seq = np.array([1, 2, 3, 4, 5])
>>> get_extended_ZF(root_seq, 8)
array([1, 2, 3, 4, 5, 1, 2, 3])
```

```
pyphysim.reference_signals.zadoffchu.get_shifted_root_seq(root_seq:
                                                         numpy.ndarray, n_cs:
                                                         int, denominator: int)
                                                         → numpy.ndarray
```

Get the shifted root sequence suitable as the SRS sequence or the DMRS sequence of a user (depend on the *denominator* parameter).

Parameters

- **root_seq** (*np.ndarray*) – The root sequence to be shifted. This is a complex numpy array.
- **n_cs** (*int*) – The desired cyclic shift number. This should be an integer from 0 to *denominator*-1, where 0 will just return the base sequence, 1 gives the first shift, and so on.
- **denominator** (*int*) – The denominator in the cyclic shift formula. This should be 8 for SRS and 12 for DMRS.

Returns The shifted root sequence (a complex numpy array).

Return type *np.ndarray*

See also:

`get_srs_seq()`, `get_dmrs_seq()`

Module contents

Package for Uplink Reference Signals related functionality.

pyphysim.simulations package

Submodules

pyphysim.simulations.configobjvalidation module

Module implementing validation functions to define “specs” for configobj validation.

This module is not intended to be used directly. The functions defined here are used in the other modules in the *pyphysim.simulations* package.

```
pyphysim.simulations.configobjvalidation.integer_numpy_array_check (value: str,  
                                                                    min: Optional[int]  
                                                                    = None,  
                                                                    max: Optional[int]  
                                                                    = None)  
                                                                    →  
                                                                    List[int]
```

Parse and validate *value* as a numpy array (of integers).

Value can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.

Parameters

- **value** (*str*) – The string to be converted. This can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.
- **min** (*int*) – The minimum allowed value. If the converted value is (or have) lower than *min* then the `VdtValueTooSmallError` exception will be raised.
- **max** (*int*) – The maximum allowed value. If the converted value is (or have) greater than *man* then the `VdtValueTooSmallError` exception will be raised.

Returns The parsed numpy array.

Return type List[int]

Notes

You can either separate the values with commas or spaces (any comma will have the same effect as a space). However, if you separate with spaces the values should be brackets, while if you separate with commands there should be no brackets.

```
>> max_iter = 5,10:20 >> max_iter = [0 5 10:20]
```

```
pyphysim.simulations.configobjvalidation.integer_scalar_or_integer_numpy_array_check (value:  
                                                                    str,  
                                                                    min:  
                                                                    Optional[int]  
                                                                    =  
                                                                    None,  
                                                                    max:  
                                                                    Optional[int]  
                                                                    =  
                                                                    None)  
                                                                    →  
                                                                    Union[int,  
                                                                    List[int]]
```

Parse and validate *value* as an integer number if possible and, if not, parse it as a numpy array (of integers).

Value can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions. The difference regarding the `integer_numpy_array_check` function is that if value is a single number it will be parsed as a single integer value, instead of being parsed as an integer numpy array with a single element.

Parameters

- **value** (*str*) – The string to be converted. This can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.
- **min** (*int*) – The minimum allowed value. If the converted value is (or have) lower than *min* then the VdtValueTooSmallError exception will be raised.
- **max** (*int*) – The maximum allowed value. If the converted value is (or have) greater than *man* then the VdtValueTooSmallError exception will be raised.

Returns The parsed numpy array.

Return type int | List[int]

Notes

You can either separate the values with commas or spaces (any comma will have the same effect as a space). However, if you separate with spaces the values should be brackets, while if you separate with commands there should be no brackets.

```
>> max_iter = 5,10:20 >> max_iter = [0 5 10:20]
```

```
pyphysim.simulations.configobjvalidation.real_numpy_array_check (value:      str,
                                                                    min:      Op-
                                                                    tional[int] =
                                                                    None,    max:
                                                                    Optional[int]
                                                                    = None)
```

Parse and validate *value* as a numpy array (of floats).

Value can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.

Parameters

- **value** (*str*) – The string to be converted. This can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.
- **min** (*int*) – The minimum allowed value. If the converted value is (or have) lower than *min* then the VdtValueTooSmallError exception will be raised.
- **max** (*int*) – The maximum allowed value. If the converted value is (or have) greater than *man* then the VdtValueTooSmallError exception will be raised.

Returns The parsed numpy array.

Return type List[float]

Notes

You can either separate the values with commas or spaces (any comma will have the same effect as a space). However, if you separate with spaces the values should be in brackets, while if you separate with commands there should be no brackets.

```
>> SNR = 0,5,10:20 >> SNR = [0 5 10:20]
```

```
pyphysim.simulations.configobjvalidation.real_scalar_or_real_numpy_array_check(value:  
    str,  
    min=None,  
    max=None)
```

Parse and validate *value* as a float number if possible and, if not, parse it as a numpy array (of floats).

Value can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions. The difference regarding the *real_numpy_array_check* function is that if value is a single number it will be parsed as a single float value, instead of being parsed as a real numpy array with a single element.

Parameters

- **value** (*str* | *list[str]*) – The string to be converted. This can be either a single number, a range expression in the form of min:max or min:step:max, or even a list containing numbers and range expressions.
- **min** (*int* | *float*) – The minimum allowed value. If the converted value is (or have) lower than *min* then the *VdtValueTooSmallError* exception will be raised.
- **max** (*int* | *float*) – The maximum allowed value. If the converted value is (or have) greater than *man* then the *VdtValueTooSmallError* exception will be raised.

Returns The parsed numpy array.

Return type float | List[float]

Notes

You can either separate the values with commas or spaces (any comma will have the same effect as a space). However, if you separate with spaces the values should be in brackets, while if you separate with commands there should be no brackets.

```
>> SNR = 0,5,10:20 >> SNR = [0 5 10:20]
```

pyphysim.simulations.parameters module

Module containing simulation parameter classes.

```
class pyphysim.simulations.parameters.SimulationParameters
```

Bases: *pyphysim.util.serialize.JsonSerializable*

Class to store the simulation parameters.

A *SimulationParameters* object acts as a container for all simulation parameters. To add a new parameter to the object just call the *add()* method passing the name and the value of the parameter. The value can be anything as long as the *SimulationRunner._run_simulation()* method can understand it.

Alternatively, you can create a *SimulationParameters* object with all the parameters with the static method *create()*, which receives a dictionary with the parameter names as keys.

Parameters can be marked to be “unpacked”, as long as they are iterable, by calling the `set_unpack_parameter()` method. Different simulations will be performed for every combination of parameters marked to be unpacked, with the other parameters kept constant.

Examples

- Create a new empty `SimulationParameters` object and add the individual parameters to it by calling its `add()` method.

```
params = SimulationParameters()
params.add('p1', [1,2,3])
params.add('p2', ['a','b'])
params.add('p3', 15)
```

- Creating a new `SimulationParameters` object with the static `create()` function.

```
p = {'p1':[1,2,3], 'p2':['a','b'], 'p3':15}
params=SimulationParameters.create(p)
params.set_unpack_parameter('p1')
params.set_unpack_parameter('p2')
```

- We can then set some of the parameters to be unpacked with

```
params.set_unpack_parameter('p1')
```

See also:

`SimulationResults` Class to store simulation results.

`SimulationRunner` Base class to implement Monte Carlo simulations.

`static _create` (*params_dict*, *unpack_index=-1*, *original_sim_params=None*)

Creates a new `SimulationParameters` object.

This static method provides a different way to create a `SimulationParameters` object, already containing the parameters in the *params_dict* dictionary.

Parameters

- **`params_dict`** (*dict*) – Dictionary containing the parameters. Each dictionary key corresponds to a parameter’s name, while the dictionary value corresponds to the actual parameter value..
- **`unpack_index`** (*int*) – Index of the created `SimulationParameters` object when it is part of the unpacked variations of another `SimulationParameters` object. See `get_unpacked_params_list()`.
- **`original_sim_params`** (`SimulationParameters`) – The original `SimulationParameters` object from which the `SimulationParameters` object that will be created by this method came from.

Returns `sim_params` – The corresponding `SimulationParameters` object.

Return type `SimulationParameters`

`static _from_dict` (*d*)

Create a new `SimulationParameters` object from a dictionary.

Parameters *d* (*dict*) – The dictionary with the data.

Returns The new SimulationParameters object.

Return type *SimulationParameters*

`_to_dict()`

Convert the SimulationParameters object to a dictionary for easier further serialization.

`add(name, value)`

Adds a new parameter to the SimulationParameters object.

If there is already a parameter with the same name it will be replaced.

Parameters

- **name** (*str*) – Name of the parameter.
- **value** (*anything*) – Value of the parameter.

`static create(params_dict)`

Creates a new SimulationParameters object.

This static method provides a different way to create a SimulationParameters object, already containing the parameters in the *params_dict* dictionary.

Parameters **params_dict** (*dict*) – Dictionary containing the parameters. Each dictionary key corresponds to a parameter's name, while the dictionary value corresponds to the actual parameter value..

Returns **sim_params** – The corresponding SimulationParameters object.

Return type *SimulationParameters*

`property fixed_parameters`

Names of the parameters which are NOT marked to be unpacked.

Returns List with the names of the fixed parameter.

Return type *list[str]*

`get_num_unpacked_variations()`

Get the number of variations when the parameters are unpacked.

If no parameter was marked to be unpacked, then return 1.

If this SimulationParameters object is actually a 'unpacked variation' of another SimulationParameters object, return the number of variations of the parent SimulationParameters object instead.

Returns **num** – The number of variations when the parameters are unpacked.

Return type *int*

`get_pack_indexes(fixed_params_dict=None)`

When you call the function `get_unpacked_params_list` you get a list of SimulationParameters objects corresponding to all combinations of the parameters. The function `get_pack_indexes` allows you to provide all parameters marked to be unpacked except one, and returns the indexes of the list returned by `get_unpacked_params_list` that you want.

Parameters **fixed_params_dict** (*dict[str, anything]*) – A dictionary with the name of the fixed parameters as keys and the fixed value as value.

Returns **indexes** – The desired indexes (1D numpy array or an integer).

Return type *np.ndarray*

Examples

Suppose we have

```
>>> p={'p1':[1,2,3], 'p2':['a','b'],'p3':15}
>>> params=SimulationParameters.create(p)
>>> params.set_unpack_parameter('p1')
>>> params.set_unpack_parameter('p2')
```

If we call `params.get_unpacked_params_list` we will get a list of six `SimulationParameters` objects, one for each combination of the values of `p1` and `p2`. That is,

```
>>> len(params.get_unpacked_params_list())
6
```

Likewise, in the simulation the `SimulationRunner` object will return a list of results in the order corresponding to the order of the list of parameters. The `get_pack_indexes` is used to get the index of the results corresponding to a specific configuration of parameters. Suppose now you want the results when 'p2' is varying, but with the other parameters fixed to some specific value. For this create a dictionary specifying all parameters except 'p2' and call `get_pack_indexes` with this dictionary. You will get an array of indexes that can be used in the results list to get the desired results. For instance

```
>>> fixed={'p1':3,'p3':15}
>>> indexes = params.get_pack_indexes(fixed)
>>> index0 = indexes[0]
>>> index1 = indexes[1]
>>> unpacked_list = params.get_unpacked_params_list()
>>> unpacked_list[index0]['p1']
3
>>> unpacked_list[index0]['p3']
15
>>> unpacked_list[index1]['p1']
3
>>> unpacked_list[index1]['p3']
15
```

`get_unpacked_params_list()`

Get a list of `SimulationParameters` objects, each one corresponding to a possible combination of (unpacked) parameters.

Returns A list of `SimulationParameters` objects.

Return type `list[SimulationParameters]`

Examples

Suppose you have a `SimulationParameters` object with the parameters 'a', 'b', 'c' and 'd' as below

```
>>> simparams = SimulationParameters()
>>> simparams.add('a', 1)
>>> simparams.add('b', 2)
>>> simparams.add('c', [3, 4])
>>> simparams.add('d', [5, 6])
```

and the parameters 'c' and 'd' were set to be unpacked.

```
>>> simparams.set_unpack_parameter('c')
>>> simparams.set_unpack_parameter('d')
```

Then `get_unpacked_params_list` would return a list of four `SimulationParameters` objects as below

```
>>> len(simparams.get_unpacked_params_list())
4
```

That is

```
[{'a': 1, 'c': 3, 'b': 2, 'd': 5},
 {'a': 1, 'c': 3, 'b': 2, 'd': 6},
 {'a': 1, 'c': 4, 'b': 2, 'd': 5},
 {'a': 1, 'c': 4, 'b': 2, 'd': 6}]
```

static load_from_config_file (*filename*, *spec=None*, *save_parsed_file=False*)

Load the `SimulationParameters` from a config file using the `configobj` module.

If the config file has a parameter called `unpacked_parameters`, which should be a list of strings with the names of other parameters, then these parameters will be set to be unpacked.

Parameters

- **filename** (*str*) – Name of the file from where the results will be loaded.
- **spec** (*list[str]*, *optional*) – A list of strings with the config spec. See “validation” in the `configobj` module documentation for more info.
- **save_parsed_file** (*bool*) – If *save_parsed_file* is `True`, then the parsed config file will be written back to disk. This will add any missing values in the config file whose default values are provided in the *spec*. This will even create the file if all default values are provided in *spec* and the file does not exist yet.

Notes

Besides the usual checks that the `configobj` validation has such as `integer`, `string`, `option`, etc., you can also use `real_numpy_array` for numpy float arrays. Note that when this validation function is used you can set the array in the config file in several ways such as

SNR=0,5,10,15:20

for instance.

static load_from_pickled_file (*filename*)

Load the `SimulationParameters` from the file ‘*filename*’ previously stored (using pickle) with *save_to_pickled_file*.

Parameters **filename** (*str*) – Name of the file from where the results will be loaded.

Returns The loaded `SimulationParameters` object.

Return type *SimulationParameters*

remove (*name*)

Remove the parameter with name *name* from the `SimulationParameters` object

Parameters **name** (*str*) – Name of the parameter to be removed.

Raises `KeyError` – If *name* is not in parameters.

save_to_pickled_file (*filename*)

Save the SimulationParameters object to the file *filename* using pickle.

Parameters *filename* (*str*) – Name of the file to save the parameters.

set_unpack_parameter (*name*, *unpack_bool=True*)

Set the unpack property of the parameter with name *name*.

The parameter *name* must be already added to the SimulationParameters object and be an iterable.

This is used in the *SimulationRunner* class.

Parameters

- **name** (*str*) – Name of the parameter to be unpacked.
- **unpack_bool** (*bool*, *optional*) – True activates unpacking for *name*, False deactivates it.

Raises *ValueError* – If *name* is not in parameters or is not iterable.

property unpack_index

Get method for the unpack_index property.

Returns The unpack index. If this SimulationParameters object is not an unpacked SimulationParameters then -1 is returned.

Return type *int*

property unpacked_parameters

Names of the parameters marked to be unpacked.

Returns

Return type *list[str]*

`pyphysim.simulations.parameters.combine_simulation_parameters` (*params1*,
params2)

Combine two SimulationParameters objects and return a new SimulationParameters object corresponding to the union of them.

The union is only valid if both objects have the same parameters and only the values of the unpacked parameters are different.

Parameters

- **params1** (*SimulationParameters*) – The first SimulationParameters object.
- **params2** (*SimulationParameters*) – The second SimulationParameters object.

Returns *union* – The union of ‘params1’ and ‘params2’.

Return type *SimulationParameters*

pyphysim.simulations.results module

Module containing simulation result classes.

```
class pyphysim.simulations.results.Result (name: str, update_type_code: int, accumulate_values: bool = False, choice_num: Optional[int] = None)
```

Bases: `pyphysim.util.serialize.JsonSerializable`

Class to store a single simulation result.

A simulation result can be anything, such as the number of errors, a string, an error rate, etc. When creating a *Result* object one needs to specify only the *name* of the stored result and the result *type*.

The different types indicate how multiple samples (from multiple iterations) of the same *Result* can be merged (usually to get a result with more statistical reliability). The possible values are *SUMTYPE*, *RATIOTYPE* and *MISCTYPE*.

In the *SUMTYPE* the new value should be added to current one in update function.

In the *RATIOTYPE* the new value should be added to current one and total should be also updated in the update function. One caveat is that rates are stored as a number (numerator) and a total (denominator) instead of as a float. For instance, if you need to store a result such as a bit error rate, then you could use the a *Result* with the *RATIOTYPE* type and when updating the result, pass the number of bit errors and the number of simulated bits.

The *MISCTYPE* type can store anything and the update will simple replace the stored value with the current value.

Parameters

- **name** (*str*) – Name of the Result.
- **update_type_code** (*int*) – Type of the result. It must be one of the elements in {Result.SUMTYPE, Result.RATIOTYPE, Result.MISCTYPE, Result.CHOICETYPE}.
- **accumulate_values** (*bool*) – If True, then the values *value* and *total* will be accumulated in the *update* (and *merge*) method(s). This means that the *Result* object will use more memory as more and more values are accumulated, but having all values sometimes is useful to perform statistical calculations. This is useful for debugging/testing.
- **choice_num** (*int*) – Number of different choices for the CHOICETYPE type. This is a required parameter for the CHOICETYPE type, but it is ignored for the other types

Examples

- Example of the SUMTYPE result.

```
>>> result1 = Result("name", Result.SUMTYPE)
>>> result1.update(13)
>>> result1.update(4)
>>> result1.get_result()
17
>>> result1.num_updates
2
>>> result1
Result -> name: 17
>>> result1.type_name
'SUMTYPE'
>>> result1.type_code
0
```

- Example of the RATIOtype result.

```
>>> result2 = Result("name2", Result.RATIOtype)
>>> result2.update(4,10)
>>> result2.update(3,4)
>>> result2.get_result()
0.5
>>> result2.type_name
'RATIOtype'
>>> result2.type_code
1
>>> result2_other = Result("name2", Result.RATIOtype)
>>> result2_other.update(3,11)
>>> result2_other.merge(result2)
>>> result2_other.get_result()
0.4
>>> result2_other.num_updates
3
>>> result2_other._value
10
>>> result2_other._total
25
>>> result2.get_result()
0.5
>>> print(result2_other)
Result -> name2: 10/25 -> 0.4
```

- Example of the MISCType result.

The MISCType result ‘merge’ process in fact simple replaces the current stored value with the new value.

CHOICEType = 3

MISCType = 2

RATIOtype = 1

SUMType = 0

_all_types = {0: 'SUMType', 1: 'RATIOtype', 2: 'MISCType', 3: 'CHOICEType'}

static _from_dict (*d*: Dict[str, Any]) → *pyphysim.simulations.results.Result*

Convert from a dictionary to a Result object.

Parameters *d* (*dict*) – The dictionary representing the Result.

Returns The converted object.

Return type *Result*

_to_dict () → Dict[str, Any]

Convert the Result object to a dictionary representation.

Returns The dictionary representation of the object.

Return type *dict*

property accumulate_values *bool*

Property to see if values are accumulated or not during a call to the *update* method.

static create (*name*: str, *update_type*: int, *value*: Any, *total*: int = 0, *accumulate_values*: bool = False) → *pyphysim.simulations.results.Result*

Create a Result object and update it with *value* and *total* at the same time.

Equivalent to creating the object and then calling its `update()` method.

Parameters

- **name** (*str*) – Name of the Result.
- **update_type** (*int*) – Type of the result. It must be one of the elements in {Result.SUMTYPE, Result.RATIOTYPE, Result.MISCTYPE, Result.CHOICETYPE}.
- **value** (*any*) – Value of the result.
- **total** (*any | int | float*) – Total value of the result (used only for the RATIO-TYPE and CHOICETYPE). For the CHOICETYPE it is interpreted as the number of different choices if it is an integer or the current value of each choice if it is a list.
- **accumulate_values** (*bool*) – If True, then the values *value* and *total* will be accumulated in the *update* (and *merge*) method(s). This means that the Result object will use more memory as more and more values are accumulated, but having all values sometimes is useful to perform statistical calculations. This is useful for debugging/testing.

Returns The new Result object.

Return type *Result*

Notes

Even if `accumulate_values` is True the values will not be accumulated for the MISCTYPE.

See also:

`update()`

get_confidence_interval (*P: float = 95.0*) → *numpy.ndarray*

Get the confidence interval that contains the true result with a given probability *P*.

Parameters *P* (*float*) – The desired confidence (probability in %) that true value is inside the calculated interval. The possible values are described in the documentation of the `calc_confidence_interval()` function`

Returns *Interval* – Numpy (float) array with two elements.

Return type *np.ndarray*

See also:

`calc_confidence_interval()`

get_result () → *Any*

Get the result stored in the Result object.

Returns *results* – For the RATIO-TYPE type `get_result` will return the *value/total*, while for the other types it will return *value*.

Return type anything, but usually a number

get_result_accumulated_totals () → *List[Any]*

Return the accumulated values.

Note that in case the result is of type RATIO-TYPE this you probably want to call the `get_result_accumulated_values` function to also get the values.

get_result_accumulated_values () → *List[Any]*

Return the accumulated values.

Note that in case the result is of type RATIOtype this you probably want to call the `get_result_accumulated_totals` function to also get the totals.

get_result_mean () → float

Get the mean of all the updated results.

Returns The mean of the result.

Return type float

get_result_var () → float

Get the variance of all updated results.

Returns The variance of the results.

Return type float

merge (other: `pyphysim.simulations.results.Result`) → None

Merge the result from other with self.

Parameters other (`Result`) – Another Result object.

property type_code

Get the Result type.

Returns `type_code` – The returned value is a number corresponding to one of the types SUMTYPE, RATIOtype, MISCTYPE or CHOICETYPE.

Return type int

property type_name

Get the Result type name.

Returns `type_name` – The result type string (SUMTYPE, RATIOtype, MISCTYPE or CHOICETYPE).

Return type str

update (value: Any, total: Optional[Any] = None) → None

Update the current value.

Parameters

- **value** (*anything, but usually a number*) – Value to be added to (or replaced) the current value
- **total** (same type as *value*) – Value to be added to the current total (only useful for the RATIOtype update type)

Notes

The way how this update process depends on the Result type and is described below

- RATIOtype: Add “value” to current value and “total” to current total.
- SUMTYPE: Add “value” to current value. “total” is ignored.
- MISCTYPE: Replace the current value with “value”.
- CHOICETYPE: Update the choice “value” and the total by 1.

See also:

`create()`

class pyphysim.simulations.results.**SimulationResults**

Bases: *pyphysim.util.serialize.JsonSerializable*

Store results from simulations.

This class is used in the *SimulationRunner* class in order to store results from a simulation. It is able to combine the results from multiple iterations (of the *SimulationRunner._run_simulation()* method in the *SimulationRunner* class) as well as append results for different simulation parameters configurations.

Note: Each result stored in the *SimulationResults* object is in fact an object of the *Result* class. This is required so that multiple *SimulationResults* objects can be merged together, since the logic to merge each individual result is in the *Result* class.

Examples

- Creating a *SimulationResults* object and adding a few results to it

```
result1 = Result.create(...) # See the Result class for details
result2 = Result.create(...)
result3 = Result.create(...)
simresults = SimulationResults()
simresults.add_result(result1)
simresults.add_result(result2)
simresults.add_result(result3)
```

Instead of explicitly create a *Result* object and add it to the *SimulationResults* object, we can also create the *Result* object on-the-fly when adding it to the *SimulationResults* object by using the *add_new_result()* method.

That is

```
simresults = SimulationResults()
simresults.add_new_result(...)
simresults.add_new_result(...)
simresults.add_new_result(...)
```

- Merging multiple *SimulationResults* objects

```
# First SimulationResults object
simresults = SimulationResults()
# Create a Result object
result = Result.create('some_name', Result.SUMTYPE, 4)
# and add it to the SimulationResults object.
simresults.add_result(result)

# Second SimulationResults object
simresults2 = SimulationResults()
# We can also create the Result object on-the-fly when adding it
# to the SimulationResults object to save one line.
simresults2.add_new_result('some_name', Result.SUMTYPE, 6)

# We can merge the results in the second SimulationResults object.
# Since the update type of the single result stored is SUMTYPE,
# then the simresults will now have a single Result of SUMTYPE
# type with a value of 10.
simresults.merge_all_results(simresults2)
```

See also:

`runner.SimulationRunner` Base class to implement Monte Carlo simulations.

`parameters.SimulationParameters` Class to store the simulation parameters.

`Result` Class to store a single simulation result.

`static _from_dict (d: Dict[str, Any]) → pyphysim.simulations.results.SimulationResults`
Convert from a dictionary to a SimulationResults object.

Parameters **d** (*dict*) – The dictionary representing the SimulationResults.

Returns The converted object.

Return type *SimulationResults*

`static _load_from_json_file (filename: str) → pyphysim.simulations.results.SimulationResults`

`static _load_from_pickle_file (filename: str) → pyphysim.simulations.results.SimulationResults`

`_save_to_json (filename: str) → None`

Save the SimulationResults object to the json file with name *filename*.

Parameters **filename** (*src*) – Name of the file to save the SimulationResults object.

`_save_to_pickle (filename: str) → None`

Save the SimulationResults object to the pickle file with name *filename*.

Parameters **filename** (*src*) – Name of the file to save the SimulationResults object.

`_to_dict () → Dict[str, Any]`

Convert the SimulationResults object to a dictionary representation.

Returns The dictionary representation of the SimulationResults object.

Return type *dict*

`add_new_result (name: str, update_type: int, value: Any, total: Any = 0) → None`

Create a new Result object on the fly and add it to the SimulationResults object.

Note: This is Equivalent to the code below,

```
result = Result.create(name, update_type, value, total)
self.add_result(result)
```

which in fact is exactly how this method is implemented.

Parameters

- **name** (*str*) – Name of the Result.
- **update_type** (*int*) – Type of the result (SUMTYPE, RATIOTYPE, MISCTYPE or CHOICETYPE).
- **value** (*any*) – Value of the result.
- **total** (*any | int*) – Total value of the result (used only for the RATIOTYPE and ignored for the other types).

add_result (*result*: `pyphysim.simulations.results.Result`) → `None`

Add a result object to the SimulationResults object.

Note: If there is already a result stored with the same name, this will replace it.

Parameters **result** (`Result`) – The Result object to add to the simulation results.

append_all_results (*other*: `pyphysim.simulations.results.SimulationResults`) → `None`

Append all the results of the other SimulationResults object with self.

Parameters **other** (`SimulationResults`) – Another SimulationResults object

See also:

`append_result()`, `merge_all_results()`

append_result (*result*: `pyphysim.simulations.results.Result`) → `None`

Append a result to the SimulationResults object.

This effectively means that the SimulationResults object will now store a list for the given result name. This allow you, for instance, to store multiple bit error rates with the ‘BER’ name such that `simulation_results_object[‘BER’]` will return a list with the Result objects for each value.

Parameters **result** (`Result`) – The Result object to append to the simulation results.

Notes

If multiple values for some Result are stored, then only the last value can be updated with `merge_all_results()`.

Raises **ValueError** – If the *result* has a different type from the result previously stored.

See also:

`append_all_results()`, `merge_all_results()`

get_filename_with_replaced_params (*filename*: `str`) → `str`

Perform the string replacements in filename with simulation parameters.

Parameters **filename** (`str`) – Name of the file to save the results. This can have string placements for replacements of simulation parameters. For instance, if *filename* is “some-name_{age}.pickle” and the value of an ‘age’ parameter is ‘3’, then the actual name used to save the file will be “somename_3.pickle”

Returns The name of the file where the results were saved. This will be equivalent to *filename* after string replacements (with the simulation parameters) are done.

Return type `string`

get_result_names () → `List[str]`

Get the names of all results stored in the SimulationResults object.

Returns **names** – The names of the results stored in the SimulationResults object.

Return type `list[str]`

get_result_values_confidence_intervals (*result_name*: `str`, *P*: `float` = 95.0, *fixed_params*: `Optional[Dict[str, Any]]` = `None`) → `List[numpy.ndarray]`

Get the values for the results with name *result_name*.

This method is similar to the `get_result_values_list` method, but instead of returning a list with the values it will return a list with the confidence intervals for those values.

Parameters

- **result_name** (*str*) – The name of the desired result.
- **P** (*float*) –
- **fixed_params** (*dict*) – A python dictionary containing the fixed parameters. If *fixed_params* is provided then the returned list will be only a subset of the results that match the fixed values of the parameters in the *fixed_params* argument, where the key is the parameter's name and the value is the fixed value. See the notes in the documentation of `get_result_values_list()` for an example.

Returns **confidence_interval_list** – A list of Numpy (float) arrays. Each element in the list is an array with two elements, corresponding to the lower and upper limits of the confidence interval.⁸

Return type `list[np.ndarray]`

See also:

`calc_confidence_interval()`

get_result_values_list (*result_name: str, fixed_params: Optional[Dict[str, Any]] = None*) → `List[Any]`

Get the values for the results with name *result_name*.

Returns a list with the values.

Parameters

- **result_name** (*str*) – The name of the desired result.
- **fixed_params** (*dict*) – A python dictionary containing the fixed parameters. If *fixed_params* is provided then the returned list will be only a subset of the results that match the fixed values of the parameters in the *fixed_params* argument, where the key is the parameter's name and the value is the fixed value. See the notes for an example.

Returns **result_list** – A list with the stored values for the result with name *result_name*

Return type `List`

Notes

As an example of the usage of the *fixed_params* argument, suppose the results were obtained in a simulation for three parameters: 'first', with value 'A', 'second' with value '[1, 2, 3]' and 'third' with value '[B, C]', where the 'second' and 'third' were set to be unpacked. In that case the returned result list would have a length of 6 (the number of possible combinations of the parameters to be unpacked). If *fixed_params* is provided with the value of "{ 'second': 2 }" that means that only the subset of results which corresponding to the second parameters having the value of '2' will be provided and the returned list will have a length of 2. If *fixed_params* is provided with the value of "{ 'second': '1', 'third': 'C' }" then a single result will be provided instead of a list.

static load_from_file (*filename: str*) → `pyphysim.simulations.results.SimulationResults`
Load the SimulationResults from the file *filename*.

Parameters **filename** (*src*) – Name of the file from where the results will be loaded.

Returns The SimulationResults object loaded from the file *filename*.

Return type `SimulationResults`

merge_all_results (*other*: `pyphysim.simulations.results.SimulationResults`) → `None`

Merge all the results of the other `SimulationResults` object with the results in self.

When there is more then one result with the same name stored in self (for instance two bit error rates -> for different parameters) then only the last one will be merged with the one in *other*. That also means that only one result for that name should be stored in *other*.

Parameters *other* (`SimulationResults`) – Another `SimulationResults` object

See also:

`append_result()`, `append_all_results()`

Notes

This method is used in the `SimulationRunner` class to combine results of two simulations for the exact same parameters.

property params

Get method for the params property.

save_to_file (*filename*: `str`) → `str`

Save the `SimulationResults` to the file *filename*.

The string in *filename* can have placeholders for string replacements with any parameter value.

Parameters *filename* (`src`) – Name of the file to save the results. This can have string placements for replacements of simulation parameters. For instance, if *filename* is “some-name_{age}.pickle” and the value of an ‘age’ parameter is ‘3’, then the actual name used to save the file will be “somename_3.pickle”

Returns The name of the file where the results were saved. This will be equivalent to *filename* after string replacements (with the simulation parameters) are done.

Return type `string`

set_parameters (*params*: `pyphysim.simulations.parameters.SimulationParameters`) → `None`

Set the parameters of the simulation used to generate the simulation results stored in the `SimulationResults` object.

Parameters *params* (`SimulationParameters`) – A `SimulationParameters` object containing the simulation parameters.

to_dataframe () → `pandas.core.frame.DataFrame`

Convert the `SimulationResults` object to a pandas `DataFrame`.

`pyphysim.simulations.results.combine_simulation_results` (*simresults1*: `py-`
`physim.simulations.results.SimulationResults`,
simresults2: `py-`
`physim.simulations.results.SimulationResults`)
→ `py-`
`physim.simulations.results.SimulationResults`

Combine two `SimulationResults` objects with different parameters values.

For this function to work both simulation objects need to have exact the same parameters and only the values of the parameters set to be unpacked can be different.

Parameters

- **simresults1** (`SimulationResults`) – The first `SimulationResults` object to be combined.

- **simresults2** (*SimulationResults*) – The second *SimulationResults* object to be combined.

Returns The combined *SimulationResults* object.

Return type *SimulationResults*

Examples

If the first *SimulationResults* object was obtained for the parameters “p1 = 10” and “p2 = [1, 2, 3]”, while the second *SimulationResults* object was obtained for the parameters “p1 = 10” and “p2 = [2, 4, 6]” and p2 was marked to be unpacked in both of them, then the returned combined *SimulationResults* object will have parameters “p1 = 10” and “p2 = [1, 2, 3, 4, 6]” with p2 marked to be unpacked.

Note that the results for the values of p2 equal to “2” and “4” exist in both objects and will be merged together.

pyphysim.simulations.runner module

Module containing the simulation runner.

```
class pyphysim.simulations.runner.SimulationRunner (default_config_file: Optional[str] = None, config_spec: Optional[str] = None, read_command_line_args: bool = True, save_parsed_file: bool = False)
```

Bases: *object*

Base class to run Monte Carlo simulations.

The main idea of the *SimulationRunner* class is that in order to implement a Monte Carlo simulation one would subclass *SimulationRunner* and implement the *_run_simulation()* method (as well as any of the optional methods). The complete procedure is described in the documentation of the *simulations* module.

Note: If a given run of *_run_simulation* cannot finish and save results for some reason then you should raise a *SkipThisOne* exception. For instance if your *_run_simulation* implementation inverts a matrix for some reason and in rare cases the matrix you are trying to invert might be singular. You might want to raise a *SkipThisOne* exception if that occurs to simply “try again”.

The code below illustrates the minimum pseudo code to implement a subclass of *SimulationRunner*.

```
class SomeSimulator (SimulationRunner):
def __init__(self):
    super().__init__()
    # Do whatever you need/want

    # Add the simulation parameters to the `params` attribute.
    self.params.add('par1', par1value)
    ...
    self.params.add('parN', parNvalue)
    # Optionally set some parameter(s) to be unpacked
    self.params.set_unpack_parameter('name_of_a_parameter')

def _run_simulation(self, current_parameters):
    # Get the simulation parameters from the current_parameters
    # object. If no parameter was marked to be unpacked, then
```

(continues on next page)

(continued from previous page)

```

# current_parameters will be equivalent to self.params.
par1 = current_parameters['par1']
...
parN = current_parameters['parN']

# Do the simulation of one iteration using the parameters
# par1,...,parN from the current_parameters object.
...

# Save the results of this iteration to a SimulationResults
# object and return it
simResults = SimulationResults()
simResults.add_new_result(...) # Add one each result you want
simResults.add_new_result(...)
return simResults

```

With that, all there is left to run the simulation is to create a `SomeSimulator` object and call its `simulate()` method.

Parameters

- **default_config_file** (*str*) – Name of the config file. This will be parsed with `configobj`.
- **config_spec** (*list[str]*) – Configuration specification to validate the config file.
- **read_command_line_args** (*bool*) – If True (default), read and parse command line arguments.
- **save_parsed_file** (*bool*) – If True, the config file will be saved after it is loaded. This is useful to add the default parameters to the config file so that they can be easily changed later. Note that if the config file does not exist at all, then it will be saved regardless of the value of `save_parsed_file`.

See also:

SimulationResults Class to store simulation results.

SimulationParameters Class to store the simulation parameters.

Result Class to store a single simulation result.

static _SimulationRunner__create_default_ipyparallel_view()

Create a default view for parallel computation.

This method is run in the `simulate_in_parallel` method if a “view” is not passed.

_SimulationRunner__run_simulation_and_track_elapsed_time (*current_parameters:*

```

py-
physim.simulations.parameters.SimulationParameters
→
py-
physim.simulations.results.SimulationResults

```

Perform the `_run_simulation` method and track its execution time. This time will be added as a `Result` to the returned `SimulationResults` object from `_run_simulation`.

Parameters **current_parameters** (`SimulationParameters`) – `SimulationParameters` object with the parameters for the simulation. The `self.params` variable is not used directly. It is first unpacked in the `simulate` function which then calls `_run_simulation` for each combination of unpacked parameters.

Returns The current simulation results.

Return type *SimulationResults*

Notes

This method is called in the *simulate* and *simulate_in_parallel*.

```
_keep_going (current_params:      pyphysim.simulations.parameters.SimulationParameters,  cur-
               rent_sim_results:  pyphysim.simulations.results.SimulationResults, current_rep: int)
               → bool
```

Check if the simulation should continue or stop.

This function may be reimplemented in the derived class if a stop condition besides the number of iterations is desired. The idea is that *_run_simulation* returns a *SimulationResults* object, which is then passed to *_keep_going*, which is then in charge of deciding if the simulation should stop or not.

Parameters

- **current_params** (*SimulationParameters*) – SimulationParameters object with the parameters of the simulation.
- **current_sim_results** (*SimulationResults*) – SimulationResults object from the last iteration (merged with all the previous results)
- **current_rep** (*int*) – Number of iterations already run.

Returns **result** – True if the simulation should continue or False otherwise.

Return type *bool*

Notes

This method should be simple (it will be run many times) and SHOULD NOT modify the object.

```
_on_simulate_current_params_finish (current_params:      py-
                                     physim.simulations.parameters.SimulationParameters,
                                     current_params_sim_results:  py-
                                     physim.simulations.results.SimulationResults)
                                     → None
```

This method is called once for each simulation parameters combination after all iterations of *_run_simulation* are performed (for that combination of simulation parameters).

Parameters

- **current_params** (*SimulationParameters*) – The current combination of simulation parameters.
- **current_params_sim_results** (*SimulationResults*) – SimulationResults object with the results for the finished simulation with the parameters in *current_params*.

Notes

Because this method will run inside the `_run_simulation` method, which is called in a different process when the simulation is performed in parallel, it should only modify member variables that are only used inside `_run_simulation`.

`_on_simulate_current_params_start` (*current_params:* [pyphysim.simulations.parameters.SimulationParameters](#))
→ `None`

This method is called once for each simulation parameters combination before any iteration of `_run_simulation` is performed (for that combination of simulation parameters).

Parameters `current_params` ([SimulationParameters](#)) – The current combination of simulation parameters.

Notes

Because this method will run inside the `_run_simulation` method, which is called in a different process when the simulation is performed in parallel, it should only modify member variables that are only used inside `_run_simulation`. If any other variable is modified these changes WILL NOT be carried back to the original process.

`_on_simulate_finish` () → `None`

This method is called only once at the end of the simulate method.

`_on_simulate_start` () → `None`

This method is called only once, in the beginning of the the simulate method.

`_run_simulation` (*current_parameters:* [pyphysim.simulations.parameters.SimulationParameters](#))
→ [pyphysim.simulations.results.SimulationResults](#)

Performs one iteration of the simulation.

This function must be implemented in a subclass. It should take the needed parameters from the `params` class attribute (which was filled in the constructor of the derived class) and return the results as a [SimulationResults](#) object.

Note that `_run_simulation` will be called `self.rep_max` times (or less if an early stop criteria is reached, which requires reimplementing the `_keep_going` function in the derived class) and the results from multiple repetitions will be merged.

Parameters `current_parameters` ([SimulationParameters](#)) – [SimulationParameters](#) object with the parameters for the simulation. The `self.params` variable is not used directly. It is first unpacked in the `simulate` function which then calls `_run_simulation` for each combination of unpacked parameters.

Returns `simulation_results` – A [SimulationResults](#) object containing the simulation results of the run iteration.

Return type [SimulationResults](#)

`_simulate_common_setup` ()

Common setup code that must run in the beginning of a simulation.

`_simulate_for_current_params_common` (*current_params:* [pyphysim.simulations.parameters.SimulationParameters](#),
update_progress_func: [Callable\[\[int\], None\]](#)) = `<function SimulationRunner.<lambda>>>` → [Tuple\[int, pyphysim.simulations.results.SimulationResults, str\]](#)

Parameters

- **current_params** (*SimulationParameters*) – The current parameters
- **update_progress_func** ((*int*) → [*int*]) – The function that can be called to update the current progress.

Returns The value of *current_rep*, the current results as a *SimulationResults* object, and the name of the file storing partial results.

Return type (*int*, *SimulationResults*, *str*)

```
static _simulate_for_current_params_parallel (obj:
                                             py-
                                             physim.simulations.runner.SimulationRunner,
                                             current_params:
                                             py-
                                             physim.simulations.parameters.SimulationParameters,
                                             update_progress_func=None)
                                             →
                                             Tuple[int,
                                             py-
                                             physim.simulations.results.SimulationResults,
                                             str]
```

Simulate (parallel) for the current parameters.

Parameters

- **obj** (*SimulationRunner*) – The same as the self parameter in regular methods. The reason that this method is set to static is to allow it to be pickled.
- **current_params** (*SimulationParameters*) – The current parameters
- **update_progress_func** ((*int*) → [*int*]) – The function (or an object with `__call__` operator) that can be called to update the current progress.

Returns The value of *current_rep*, the current results as a *SimulationResults* object, and the name of the file storing partial results.

Return type (*int*, *SimulationResults*, *str*)

```
_simulate_for_current_params_serial (current_params:
                                     py-
                                     physim.simulations.parameters.SimulationParameters)
                                     →
                                     Tuple[int,
                                     py-
                                     physim.simulations.results.SimulationResults,
                                     str]
```

Simulate (serial) for the current parameters.

Parameters **current_params** (*SimulationParameters*) – The current parameters

Returns The value of *current_rep*, the current results as a *SimulationResults* object, and the name of the file storing partial results.

Return type (*int*, *SimulationResults*, *str*)

clear () → *None*

Clear the *SimulationRunner*.

This will erase any results from previous simulations as well as other internal variables. The *SimulationRunner* object will then be as if it was just created, except that the simulation parameters will be kept.

property delete_partial_results_bool

property elapsed_time

Get the simulation elapsed time. Do not set this value.

Returns The elapsed time.

Return type *float*

`property params`
`property partial_results_folder`
`property progress_output_type`
`property progressbar_message`
`property results`
`property results_filename`
`property runned_reps`

Get method for the runned_reps property.

Returns The value of the runned_reps property, which stores the number of runned repetitions for each unpacked parameters combination.

Return type `list[int]`

set_results_filename (*filename: Optional[str] = None*) → `None`

Set the name of the file where the simulation results will be saved.

This must be done before calling the *simulate* of the *simulate_in_parallel* methods.

The *filename* argument is formatted with the simulation parameters. That is, suppose there are two parameters $N_r=2$ and $N_t=1$, then if *filename* is equal to “results_for_{Nr}x{Nt}” the actual name of the file used to store the simulation results will be “results_for_2x1.pickle”.

The advantage of setting the name of the results file with *set_results_filename* instead of manually saving the results after the simulation is finished is that partial results will also be saved. Therefore the simulation can be stopped and continued later from these partial results.

Parameters filename (*str*) – The name of the file (without extension) where the simulation results will be stored. If not provided the results will not be automatically stored.

simulate (*param_variation_index: Optional[int] = None*) → `None`

Performs the full Monte Carlo simulation (serially).

Implements the general code for every simulation. Any code specific to a single simulation iteration must be implemented in the *_run_simulation* method of a subclass of *SimulationRunner*.

The main idea behind the *SimulationRunner* class is that the general code in every simulator is implemented in the *SimulationRunner* class, more specifically in the *simulate* method, while the specific code of a single iteration is implemented in the *_run_simulation* method in a subclass.

Parameters param_variation_index (*int, optional*) – If not provided, the full simulation will be run. If this is provided the simulation will be run only for the parameters variation with index given by *param_variation_index*. In that case, calling the *set_results_filename* method before the *simulate* method is required since only the partial results will be saved.

See also:

`simulate_in_parallel()`

simulate_common_cleaning ()

Common code that must run in the end of a simulation

simulate_in_parallel (*view: Optional[Union[ipyparallel.client.view.LoadBalancedView, ipyparallel.client.view.DirectView]] = None, wait: bool = True*) → `None`

Same as the *simulate* method, but the different parameters configurations are simulated in parallel.

Parameters

- **view** (*LoadBalancedView* | *DirectView*) – A ‘view’ of the IPython engines. The parallel processing will happen by calling the ‘map’ method of the provided view to simulate in parallel the different configurations of transmission parameters.
- **wait** (*bool*) – If True then the `self.wait_parallel_simulation` method will be automatically called at the end of `simulate_in_parallel`. If False, the YOU NEED to manually call `self.wait_parallel_simulation` at some point after calling `simulate_in_parallel`.

Notes

There is a limitation regarding the partial simulation results. The partial results files will be saved in the folder where the IPython engines are running, since the “saving part” is performed in an IPython engine. However, the deletion of the files is not performed in by the IPython engines, but by the main python program. Therefore, unless the Ipython engines are running in the same folder where the main python program will be run the partial result files won’t be automatically deleted after the simulation is finished.

property `update_progress_function_style`

wait_parallel_simulation() → `None`

Wait for the parallel simulation to finish and then update the `self.results` variable (as well as other internal variables).

exception `pyphysim.simulations.runner.SkipThisOne` (*msg: str*)

Bases: `Exception`

Exception that can be raised in the `_run_simulation` method to skip the current repetition.

The `simulate` method will not count a run of `_run_simulation` if it throws a `SkipThisOne` exception.

Parameters *msg* (*str*) – The message with more information on why the exception was raised.

`pyphysim.simulations.runner.get_partial_results_filename` (*results_base_filename:*

str, *current_params:* `py-`

`physim.simulations.parameters.SimulationParameters`

partial_results_folder:

Optional[str] = `None`)

→ `str`

Get the name of the file where the partial result will be saved for the unpacked result with index *unpack_index*.

Parameters

- **results_base_filename** (*str*) – Base name for partial result file.
- **current_params** (`SimulationParameters`) – The current parameters, which must be a “unpacked variation” of another `SimulationParameters` object.
- **partial_results_folder** (*str*, *optional*) – The folder where the partial results will be stored.

Returns `partial_results_filename` – The name of the partial results file.

Return type `str`

pyphysim.simulations.simulationhelpers module

Module implementing helper functions for simulators.

`pyphysim.simulations.simulationhelpers._add_folder_to_ipython_engines_path` (*client*:
ipy-
par-
al-
lel.client.client.Client,
folder:
str)
→
None

Add a folder to `sys.path` of each ipython engine.

The list of engines is get as a direct view from 'client'.

This will also add the folder to the local python path.

Parameters

- **client** (*Client*) – The client from which we will get a direct view to access the engines.
- **folder** (*str*) – The folder to be added to the python path at each engine.

`pyphysim.simulations.simulationhelpers._simulate_do_what_i_mean_multiple_runners` (*list_of_runners*:
List[pyphysim
folder:
Op-
tional[*str*]
=
None)
→
None

This will either call the *simulate* method or the *simulate_in_parallel* method as appropriated.

If the 'parameters variation index' was specified in the command line, then the *simulate* method will be called with that index. If not, then the *simulate* method will be called without any index or, if there is an ipython cluster running, the *simulate_in_parallel* method will be called.

Parameters

- **list_of_runners** (*list*[*SimulationRunner*]) – The *_simulate_do_what_i_mean_single_runner* will be called for each object in the list.
- **folder** (*str*) – Folder to be added to the python path. This should be the main pyphysim folder.

```
pyphysim.simulations.simulationhelpers._simulate_do_what_i_mean_single_runner(runner:
py-
physim.simulation
folder:
Op-
tional[str]
=
None,
block:
bool
=
True)
→
None
```

This will either call the *simulate* method or the *simulate_in_parallel* method as appropriated.

If the ‘parameters variation index’ was specified in the command line, then the *simulate* method will be called with that index. If not, then the *simulate* method will be called without any index or, if there is an ipython cluster running, the *simulate_in_parallel* method will be called.

Parameters

- **runner** (*SimulationRunner*) – The *SimulationRunner* object for which either the ‘simulate’ or the ‘simulate_in_parallel’ method will be called.
- **folder** (*str*, *optional*) – Folder to be added to the python path. This should be the main pyphysim folder
- **block** (*bool*, *optional*) – Passed to the *simulate_in_parallel* method when the simulation is performed in parallel. If this is false, you need to call the method ‘wait_parallel_simulation’ of the runner object at some point.

```
pyphysim.simulations.simulationhelpers.simulate_do_what_i_mean(runner_or_list_of_runners:
Union[pyphysim.simulations.runner.Sim
List[pyphysim.simulations.runner.Simula
folder:      Op-
tional[str]  =
None) → None
```

This will either call the *simulate* method or the *simulate_in_parallel* method as appropriated.

If the ‘parameters variation index’ was specified in the command line, then the ‘simulate’ method will be called with that index. If not, then the *simulate* method will be called without any index or, if there is an ipython cluster running, the *simulate_in_parallel* method will be called.

Parameters

- **runner_or_list_of_runners** (*SimulationRunner* | *list[SimulationRunner]*) – The *SimulationRunner* object for which either the ‘simulate’ or the ‘simulate_in_parallel’ method will be called. If this is a list, then we just call this method individually for each member of the list.
- **folder** (*str*) – Folder to be added to the python path. This should be the main pyphysim folder

Module contents

Module containing useful classes to implement Monte Carlo simulations.

The main class for Monte Carlo simulations is the `runner.SimulationRunner` class, but a few other classes are also implemented to handle simulation parameters and simulation results.

More specifically, the `simulations` module implements the classes:

- `runner.SimulationRunner`
- `parameters.SimulationParameters`
- `results.SimulationResults`
- `results.Result`

For a description of how to implement Monte Carlo simulations using the classes defined in the `simulations` module see the section *Implementing Monte Carlo simulations*.

pyphysim.subspace package

Submodules

pyphysim.subspace.metrics module

Implement several metrics for subspaces.

`pyphysim.subspace.metrics.calc_chordal_distance` (*matrix1*: `numpy.ndarray`, *matrix2*: `numpy.ndarray`) → float

Calculates the chordal distance between the two matrices

Parameters

- **matrix1** (`np.ndarray`) – A 2D numpy array.
- **matrix2** (`np.ndarray`) – A 2D numpy array.

Returns `chord_dist` – The chordal distance.

Return type float

Notes

Same as `calc_chordal_distance_2()`, but implemented differently.

See also:

`calc_chordal_distance_2()`, `calc_chordal_distance_from_principal_angles()`

Examples

```
>>> A = np.arange(1, 9.)
>>> A.shape = (4, 2)
>>> B = np.array([[1.2, 2.1], [2.9, 4.3], [5.2, 6.1], [6.8, 8.1]])
>>> print(round(calc_chordal_distance(A, B), 8))
0.47386786
```

pyphysim.subspace.metrics.**calc_chordal_distance_2** (*matrix1: numpy.ndarray, matrix2: numpy.ndarray*) → float

Calculates the chordal distance between the two matrices

Parameters

- **matrix1** (*np.ndarray*) – A 2D numpy array.
- **matrix2** (*np.ndarray*) – A 2D numpy array.

Returns **chord_dist** – The chordal distance.

Return type float

Notes

Same as `calc_chordal_distance()`, but implemented differently.

See also:

`calc_chordal_distance()`, `calc_chordal_distance_from_principal_angles()`

Examples

```
>>> A = np.arange(1, 9.)
>>> A.shape = (4, 2)
>>> B = np.array([[1.2, 2.1], [2.9, 4.3], [5.2, 6.1], [6.8, 8.1]])
>>> print(round(calc_chordal_distance_2(A, B), 8))
0.47386786
```

pyphysim.subspace.metrics.**calc_chordal_distance_from_principal_angles** (*principalAngles: numpy.ndarray*) → float

Calculates the chordal distance from the principal angles.

It is given by the square root of the sum of the squares of the sin of the principal angles.

Parameters **principalAngles** (*np.ndarray*) – Numpy array with the principal angles. This is a 1D numpy array.

Returns **chord_dist** – The chordal distance.

Return type float

See also:

`calc_principal_angles()`, `calc_chordal_distance()`, `calc_chordal_distance_2()`

Examples

```
>>> A = np.arange(1, 9.)
>>> A.shape = (4, 2)
>>> B = np.array([[1.2, 2.1], [2.9, 4.3], [5.2, 6.1], [6.8, 8.1]])
>>> princ_angles = calc_principal_angles(A, B)
>>> print(round(calc_chordal_distance_from_principal_angles(princ_angles), 8))
0.47386786
```

pyphysim.subspace.metrics.**calc_principal_angles** (*matrix1*: *numpy.ndarray*, *matrix2*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the principal angles between *matrix1* and *matrix2*.

Parameters

- **matrix1** (*np.ndarray*) – A 2D numpy array.
- **matrix2** (*np.ndarray*) – A 2D numpy array.

Returns The principal angles between *matrix1* and *matrix2*. This is a 1D numpy array.

Return type *np.ndarray*

See also:

calc_chordal_distance_from_principal_angles()

Examples

```
>>> A = np.array([[1, 2], [3, 4], [5, 6]])
>>> B = np.array([[1, 5], [3, 7], [5, -1]])
>>> print(calc_principal_angles(A, B))
[0.          0.54312217]
```

pyphysim.subspace.projections module

Module related to subspace projection.

class pyphysim.subspace.projections.**Projection** (*A*: *numpy.ndarray*)

Bases: *object*

Class to calculate the projection, orthogonal projection and reflection of a given matrix in a Subspace *S* spanned by the columns of a matrix *A*.

The matrix *A* is provided in the constructor and after that the functions *project*, *oProject* and *reflect* can be called with *M* as an argument.

Parameters **A** (*np.ndarray*) – The matrix whose columns form a basis for the projected subspace.

Examples

```
>>> A = np.array([[1 + 1j, 2 - 2j], [3 - 2j, 0], [-1 - 1j, 2 - 3j]])
>>> v = np.array([1, 2, 3])
>>> P = Projection(A)
>>> P.project(v)
array([1.69577465+0.87887324j, 1.33802817+0.41408451j,
       2.32957746-0.56901408j])
>>> P.oProject(v)
array([-0.69577465-0.87887324j,  0.66197183-0.41408451j,
       0.67042254+0.56901408j])
>>> P.reflect(v)
array([-2.3915493 -1.75774648j, -0.67605634-0.82816901j,
       -1.65915493+1.13802817j])
```

static `calcOrthogonalProjectionMatrix` (*A*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the projection matrix that projects a vector (or a matrix) into the signal space orthogonal to the signal space spanned by the columns of *M*.

Parameters *A* (*np.ndarray*) – A matrix whose columns form a basis for the “desired subspace”.

Returns The projection matrix that can be used to project a vector or a matrix into the subspace orthogonal to the subspace spanned by the columns of *A*

Return type *np.ndarray*

See also:

`calcProjectionMatrix()`

Examples

```
>>> A = np.array([[1, 2], [2, 2], [4, 3]])
>>> # Matrix that projects into the subspace orthogonal to the
>>> # subspace spanned by the columns of A
>>> oQ = calcOrthogonalProjectionMatrix(A)
>>> print(oQ)
[[ 0.12121212 -0.3030303  0.12121212]
 [-0.3030303  0.75757576 -0.3030303 ]
 [ 0.12121212 -0.3030303  0.12121212]]
```

static `calcProjectionMatrix` (*A*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the projection matrix that projects a vector (or a matrix) into the signal space spanned by the columns of *A*.

Parameters *A* (*np.ndarray*) – A matrix whose columns form a basis for the desired subspace.

Returns The projection matrix that can be used to project a vector or a matrix into the subspace spanned by the columns of *A*

Return type *np.ndarray*

See also:

`calcOrthogonalProjectionMatrix()`

Examples

```
>>> A = np.array([[1 + 1j, 2 - 2j], [3 - 2j, 0], [-1 - 1j, 2 - 3j]])
>>> # Matrix that projects into the subspace spanned by the columns
>>> # of A
>>> Q = calcProjectionMatrix(A)
>>> np.allclose(Q.round(4), np.array([[ 0.5239+0.j, 0.0366+0.3296j,
  0.3662+0.0732j], [ 0.0366-0.3296j, 0.7690+0.j, -0.0789+0.2479j],
  [ 0.3662-0.0732j, -0.0789-0.2479j, 0.7070-0.j]]))
True
```

oProject (*M*: *numpy.ndarray*) → *numpy.ndarray*

Project the matrix (or vector) *M* the subspace ORTHOGONAL to the subspace projected with *project*.

Parameters *M* (*np.ndarray*) – The matrix to be projected.

Returns The projection of *M* into the orthogonal subspace.

Return type *np.ndarray*

project (*M*: *numpy.ndarray*) → *numpy.ndarray*

Project the matrix (or vector) *M* in the desired subspace.

Parameters *M* (*np.ndarray*) – The matrix to be projected.

Returns The projection of *M* into the desired subspace.

Return type *np.ndarray*

reflect (*M*: *numpy.ndarray*) → *numpy.ndarray*

Find the reflection of the matrix in the subspace spanned by the columns of *A*

Parameters *M* (*np.ndarray*) – The matrix to be projected.

Returns The reflection of *M* in the subspace.

Return type *np.ndarray*

pyphysim.subspace.projections.calcOrthogonalProjectionMatrix (*A*: *numpy.ndarray*)
→ *numpy.ndarray*

Calculates the projection matrix that projects a vector (or a matrix) into the signal space orthogonal to the signal space spanned by the columns of *M*.

Parameters *A* (*np.ndarray*) – A matrix whose columns form a basis for the “desired subspace”.

Returns The projection matrix that can be used to project a vector or a matrix into the subspace orthogonal to the subspace spanned by the columns of *A*

Return type *np.ndarray*

See also:

calcProjectionMatrix()

Examples

```
>>> A = np.array([[1, 2], [2, 2], [4, 3]])
>>> # Matrix that projects into the subspace orthogonal to the
>>> # subspace spanned by the columns of A
>>> oQ = calcOrthogonalProjectionMatrix(A)
>>> print(oQ)
[[ 0.12121212 -0.3030303  0.12121212]
 [-0.3030303  0.75757576 -0.3030303 ]
 [ 0.12121212 -0.3030303  0.12121212]]
```

pyphysim.subspace.projections.**calcProjectionMatrix**(A: *numpy.ndarray*) → *numpy.ndarray*

Calculates the projection matrix that projects a vector (or a matrix) into the signal space spanned by the columns of A.

Parameters **A** (*np.ndarray*) – A matrix whose columns form a basis for the desired subspace.

Returns The projection matrix that can be used to project a vector or a matrix into the subspace spanned by the columns of A

Return type *np.ndarray*

See also:

calcOrthogonalProjectionMatrix()

Examples

```
>>> A = np.array([[1 + 1j, 2 - 2j], [3 - 2j, 0], [-1 - 1j, 2 - 3j]])
>>> # Matrix that projects into the subspace spanned by the columns
>>> # of A
>>> Q = calcProjectionMatrix(A)
>>> np.allclose(Q.round(4), np.array([[ 0.5239+0.j, 0.0366+0.3296j, 0.3662+0.0732j],
[ 0.0366-0.3296j, 0.7690+0.j, -0.0789+0.2479j],
[ 0.3662-0.0732j, -0.0789-0.2479j, 0.7070-0.j]]))
True
```

Module contents

Subspace related stuff.

This includes projections and metrics for subspaces.

pyphysim.util package

Submodules

pyphysim.util.conversion module

Module containing function related to several conversions, such as linear to dB, binary to gray code, as well as the inverse of them.

`pyphysim.util.conversion.EbN0_dB_to_SNR_dB` (*EbN0*: *NumberOrArray*, *bits_per_symb*: *int*)
→ *NumberOrArray*

Convert an Eb/N0 value (in dB) to the equivalent SNR value (also in dB).

Parameters

- **EbN0** – Eb/N0 value (in dB)
- **bits_per_symb** – Number of bits in a symbol.

Returns SNR value (in dB)

Return type SNR

`pyphysim.util.conversion.SNR_dB_to_EbN0_dB` (*SNR*: *NumberOrArray*, *bits_per_symb*: *int*)
→ *NumberOrArray*

Convert an SNR value (in dB) to the equivalent Eb/N0 value (also in dB).

Parameters

- **SNR** – SNR value (in dB).
- **bits_per_symb** – Number of bits in a symbol.

Returns Eb/N0 value (in dB)

Return type EbN0

`pyphysim.util.conversion.binary2gray` (*num*: *IntOrIntArray*) → *IntOrIntArray*

Convert a number (in decimal format) to the corresponding Gray code (still in decimal format).

Parameters *num* (*int* | *np.ndarray*) – The number in decimal encoding

Returns *num_gray* – Corresponding gray code (in decimal format) of *num*.

Return type *int* | *np.ndarray*

Examples

```
>>> binary2gray(np.arange(0, 8))
array([0, 1, 3, 2, 6, 7, 5, 4])
```

`pyphysim.util.conversion.dB2Linear` (*valueIndB*: *NumberOrArray*) → *NumberOrArray*

Convert input from dB to linear scale.

Parameters *valueIndB* (*int* | *float* | *np.ndarray*) – Value in dB

Returns *valueInLinear* – Value in Linear scale.

Return type *int* | *float* | *np.ndarray*

Examples

```
>>> dB2Linear(30)
1000.0
```

`pyphysim.util.conversion.dBm2Linear` (*valueIndBm*: *NumberOrArray*) → *NumberOrArray*

Convert input from dBm to linear scale.

Parameters *valueIndBm* (*int* | *float* | *np.ndarray*) – Value in dBm.

Returns *valueInLinear* – Value in linear scale.

Return type float | np.ndarray

Examples

```
>>> dBm2Linear(60)
1000.0
```

pyphysim.util.conversion.**gray2binary**(*num: IntOrIntArray*) → IntOrIntArray

Convert a number in Gray code (in decimal format) to its original value (in decimal format).

Parameters *num*(int | np.ndarray) – The number in gray coding

Returns *num_orig* – The original number (in decimal format) whose Gray code correspondent is *num*.

Return type int | np.ndarray

Examples

```
>>> gray2binary(binary2gray(np.arange(0,10)))
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
```

pyphysim.util.conversion.**linear2dB**(*valueInLinear: NumberOrArray*) → NumberOrArray

Convert input from linear to dB scale.

Parameters *valueInLinear*(int | float | np.ndarray) – Value in Linear scale.

Returns *valueIndB* – Value in dB scale.

Return type int | float | np.ndarray

Examples

```
>>> linear2dB(1000)
30.0
```

pyphysim.util.conversion.**linear2dBm**(*valueInLinear: NumberOrArray*) → NumberOrArray

Convert input from linear to dBm scale.

Parameters *valueInLinear*(float | np.ndarray) – Value in Linear scale

Returns *valueIndBm* – Value in dBm.

Return type float | np.ndarray

Examples

```
>>> linear2dBm(1000)
60.0
```

pyphysim.util.conversion.**single_matrix_to_matrix_of_matrices** (*single_matrix*:
numpy.ndarray,
nrows: *Optional*[*numpy.ndarray*]
= *None*, *ncols*: *Optional*[*numpy.ndarray*]
= *None*) →
numpy.ndarray

Converts a single numpy array to a numpy array of numpy arrays.

For instance, a 6x6 numpy array may be converted to a 3x3 numpy array of 2x2 arrays.

Parameters

- **single_matrix** (*np.ndarray*) – The single numpy array. This should be a 1D numpy array or a 2D numpy array.
- **nrows** (*np.ndarray*, *optional*) – The number of rows of each submatrix (if *single_matrix* is 2D), or the number of elements in each subarray (if *single_matrix* is 1D).
- **ncols** (*np.ndarray*, *optional*) – The number of rows of each submatrix. If *single_matrix* is a 1D array then *ncols* should be *None* (default)

Returns The converted array (1D or 2D) of arrays (1D or 2D) as a 1D or 2D numpy array of arrays.

Return type *np.ndarray*

Notes

The parameters *ncols* and *nrows* cannot both be equal to *None*.

Examples

```
>>> # Case where we have a single array
>>> single_array = np.array([2, 2, 4, 5, 6, 8, 8, 8, 8])
>>> sizes = np.array([2, 3, 4])
>>> m_of_ms = single_matrix_to_matrix_of_matrices(single_array, sizes)
>>> print(m_of_ms.size)
3
>>> print(m_of_ms[0])
[2 2]
>>> print(m_of_ms[1])
[4 5 6]
>>> print(m_of_ms[2])
[8 8 8 8]
>>>
>>> # Case where we have a matrix to break in packs of rows
>>> single_matrix = np.array([[1, 1, 1], [2, 2, 2], [3, 3, 3]])
>>> rows = np.array([1, 2])
>>> multi_M = single_matrix_to_matrix_of_matrices(single_matrix, rows)
>>> print(multi_M[0])
[[1 1 1]]
>>> print(multi_M[1])
[[2 2 2]
 [3 3 3]]
>>> # Case where we have a matrix to break in packs of columns
>>> rows = None
```

(continues on next page)

(continued from previous page)

```

>>> cols = np.array([1, 2])
>>> multi_M=single_matrix_to_matrix_of_matrices(single_matrix,
↪          rows, cols)
>>> print(multi_M[0])
[[1]
 [2]
 [3]]
>>> print(multi_M[1])
[[1 1]
 [2 2]
 [3 3]]
>>> # Case where we break into multiple matrices
>>> rows = np.array([2, 1])
>>> cols = np.array([1, 2])
>>> multi_M=single_matrix_to_matrix_of_matrices(single_matrix,
↪          rows, cols)
>>> print(multi_M[0, 0])
[[1]
 [2]]
>>> print(multi_M[0, 1])
[[1 1]
 [2 2]]

```

pyphysim.util.misc module

Module containing useful general functions that don't belong to another module.

`pyphysim.util.misc.calc_autocorr(x: numpy.ndarray) → numpy.ndarray`
 Calculates the (normalized) auto-correlation of an array *x* starting from lag 0.

Parameters *x* (*np.ndarray*) – A 1D numpy array.

Returns *result* – The normalized auto-correlation of *x*.

Return type *np.ndarray*

Examples

```

>>> x = np.array([4, 2, 1, 3, 7, 3, 8])
>>> calc_autocorr(x)
array([ 1.    , -0.025,  0.15 , -0.175, -0.25 , -0.2   ,  0.    ])

```

`pyphysim.util.misc.calc_confidence_interval(mean: float, std: float, n: int, P: float = 95.0)`
 → *Tuple[float, float]*

Calculate the confidence interval that contains the true mean (of a normal random variable) with a certain probability *P*, given the measured *mean*, standard deviation *std* for number of samples *n*.

Only a few values are allowed for the probability *P*, which are: 50%, 60%, 70%, 80%, 90%, 95%, 98%, 99%, 99.5%, 99.8% and 99.9%.

Parameters

- **mean** (*float*) – The measured mean value.
- **std** (*float*) – The measured standard deviation.
- **n** (*int*) – The number of samples used to measure the mean and standard deviation.

- **P** (*float*) – The desired confidence (probability in %) that true value is inside the calculated interval.

Returns A list with two float elements, the interval minimum and maximum values.

Return type *float, float*

Notes

This function assumes that the estimated random variable is a normal variable.

`pyphysim.util.misc.calc_decorrelation_matrix` (*cov_matrix*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the decorrelation matrix that can be applied to a data vector whose covariance matrix is *cov_matrix* so that the new vector covariance matrix is a diagonal matrix.

Parameters *cov_matrix* (*np.ndarray*) – The covariance matrix of the original data that will be decorrelated. This must be a symmetric and positive semi-definite matrix

Returns The decorrelation matrix D . If the original data is a vector it can be decorrelated with D^T .

Return type *np.ndarray*

See also:

`calc_whitening_matrix()`

`pyphysim.util.misc.calc_shannon_sum_capacity` (*sinrs*: *Union[numpy.ndarray, float]*) → *float*

Calculate the sum of the Shannon capacity of the values in *sinrs*

Parameters *sinrs* (*float* | *np.ndarray*) – SINR values (in linear scale).

Returns *sum_capacity* – Sum capacity.

Return type *float*

Examples

```
>>> calc_shannon_sum_capacity(11.4)
3.6322682154995127
>>> calc_shannon_sum_capacity(20.3)
4.412781525338476
>>> sinrs_linear = np.array([11.4, 20.3])
>>> print(calc_shannon_sum_capacity(sinrs_linear))
8.045049740837989
```

`pyphysim.util.misc.calc_unorm_autocorr` (*x*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the unnormalized auto-correlation of an array *x* starting from lag 0.

Parameters *x* (*np.ndarray*) – A 1D numpy array.

Returns *result* – The unnormalized auto-correlation of *x*.

Return type *np.ndarray*

Examples

```
>>> x = np.array([4, 2, 1, 3, 7, 3, 8])
>>> calc_unorm_autocorr(x)
array([152, 79, 82, 53, 42, 28, 32])
```

pyphysim.util.misc.**calc_whitening_matrix**(*cov_matrix*: *numpy.ndarray*) → *numpy.ndarray*

Calculates the whitening matrix that can be applied to a data vector whose covariance matrix is *cov_matrix* so that the new vector covariance matrix is an identity matrix

Parameters *cov_matrix* (*np.ndarray*) – The covariance matrix of the original data that will be decorrelated. This must be a symmetric and positive semi-definite matrix

Returns *whitening_matrix* – The whitening matrix W . If the original data is a vector it can be whitened with W^H .

Return type *np.ndarray*

Notes

The returned *whitening_matrix* matrix will make the covariance of the filtered data an identity matrix. If you only need the the covariance matrix of the filtered data to be a diagonal matrix (not necessarily an identity matrix) what you want to calculate is the “decorrelation matrix”. See the *calc_decorrelation_matrix()* function for that.

See also:

calc_decorrelation_matrix()

pyphysim.util.misc.**count_bit_errors**(*first*: *IntOrIntArray*, *second*: *IntOrIntArray*, *axis*: *Optional[Any]* = *None*) → *IntOrIntArray*

Compare *first* and *second* and count the number of equivalent bit errors.

The two arguments are assumed to have the index of transmitted and decoded symbols. The *count_bit_errors* function will compare each element in *first* with the corresponding element in *second*, determine how many bits changed and then return the total number of changes bits. For instance, if we compare the numbers 3 and 0, we see that 2 bits have changed, since 3 corresponds to ‘11’, while 0 corresponds to ‘00’.

Parameters

- **first** (*int* | *np.ndarray*) – The decoded symbols.
- **second** (*int* | *np.ndarray*) – The transmitted symbols.
- **axis** (*int*, *optional*) – Since *first* and *second* can be numpy arrays, when *axis* is not provided (that is, it is *None*) then the total number of bit errors of all the elements of the ‘difference array’ is returned. If *axis* is provided, then an array of bit errors is returned where the number of bit errors summed along the provided *axis* is returned.

Returns *bit_errors* – The total number of bit errors.

Return type *int* | *np.ndarray*

Examples

```
>>> first = np.array([[2, 3, 3, 0], [1, 3, 1, 2]])
>>> second = np.array([[0, 3, 2, 0], [2, 0, 1, 2]])
>>> # The number of changed bits in each element is equal to
>>> # array([1, 0, 1, 0, 2, 2, 0])
>>> count_bit_errors(first, second)
6
>>> count_bit_errors(first, second, 0)
array([3, 2, 1, 0])
>>> count_bit_errors(first, second, 1)
array([2, 4])
```

`pyphysim.util.misc.equal_dicts` (*a*: Dict[Any, Any], *b*: Dict[Any, Any], *ignore_keys*: List[Any])
→ bool

Test if two dictionaries are equal ignoring certain keys.

Parameters

- **a** (*dict*) – The first dictionary
- **b** (*dict*) – The second dictionary
- **ignore_keys** (*list*) – A list or tuple with the keys to be ignored.

`pyphysim.util.misc.get_mixed_range_representation` (*array*: *numpy.ndarray*, *file-*
name_mode: *bool* = *False*) →
str

Get the “range representation” of a numpy array. This is similar to `get_range_representation`, but if no pure range representation is possible it will try to represent at least part of the array as range representations.

Suppose you have the array `n = [1, 2, 3, 5, 10, 15, 20, 25, 30, 35, 40, 100]`

Except for the 3 initial and the final elements, this array is an arithmetic progression with step equal to 5. Lets keep the 3 initial and the final values and represent the other values as a range representation.

Parameters

- **array** (*np.ndarray*) – The array to be represented as a range expression.
- **filename_mode** (*bool*, *optional*) – If True, the returned representation will be more suitable to be used as part of a file-name. That is instead of “5:5:40” the string “5_(5)_40” would be returned.

Returns *expr* – A string expression representing *array*.

Return type *str*

`pyphysim.util.misc.get_principal_component_matrix` (*A*: *numpy.ndarray*,
num_components: *int*) →
numpy.ndarray

Returns a matrix without the “principal components” of *A*.

This function returns a new matrix formed by the most significant components of *A*.

Parameters

- **A** (*np.ndarray*) – The original matrix, which is a 2D numpy matrix.
- **num_components** (*int*) – Number of components to be kept.

Returns *out* – The new matrix with the dead dimensions removed.

Return type *np.ndarray*

Notes

You might want to normalize the returned matrix *out* after calling `get_principal_component_matrix` to have the same norm as the original matrix *A*.

`pyphysim.util.misc.get_range_representation` (*array*: *numpy.ndarray*, *filename_mode*: *bool* = *False*) → *Optional[str]*

Get the “range representation” of a numpy array consisting of an arithmetic progression. If no valid range representation exists, return *None*.

Suppose you have the array *n* = [5, 10, 15, 20, 25, 30, 35, 40] This array is an arithmetic progression with step equal to 5 and can be represented as “5:5:40”, which is exactly what `get_range_representation` will return for such array.

Parameters

- **array** (*np.ndarray*) – The array to be represented as a range expression.
- **filename_mode** (*bool*, *optional*) – If *True*, the returned representation will be more suitable to be used as part of a file-name. That is instead of “5:5:40” the string “5_(5)_40” would be returned.

Returns *expr* – A string expression representing *array*.

Return type *str*

`pyphysim.util.misc.gmd` (*U*: *numpy.ndarray*, *S*: *numpy.ndarray*, *V_H*: *numpy.ndarray*, *tol*: *float* = 0.0) → *Tuple[numpy.ndarray, numpy.ndarray, numpy.ndarray]*

Perform the Geometric Mean Decomposition of a matrix *A*, whose SVD is given by [*U*, *S*, *V_H*] = *np.linalg.svd(A)*.

The Geometric Mean Decomposition (GMD) is described in paper “Joint Transceiver Design for MIMO Communications Using Geometric Mean Decomposition.”

Parameters

- **U** (*np.ndarray*) – First matrix obtained from the SVD decomposition of the original matrix you want to decompose.
- **S** (*np.ndarray*) – Second matrix obtained from the SVD decomposition of the original matrix you want to decompose.
- **V_H** (*np.ndarray*) – Third matrix obtained from the SVD decomposition of the original matrix you want to decompose.
- **tol** (*float*) – The tolerance.

Returns The three matrices *Q*, *R* and *P* such that $A = QRP^H$, *R* is an upper triangular matrix and *Q* and *P* are unitary matrices.

Return type (*np.ndarray*, *np.ndarray*, *np.ndarray*)

`pyphysim.util.misc.int2bits` (*n*: *int*) → *int*

Calculates the number of bits needed to represent an integer *n*.

Parameters *n* (*int*) – The integer number.

Returns *num_bits* – The number of bits required to represent the number *n*.

Return type *int*

Examples

```
>>> list(map(int2bits, range(0,19)))
[1, 1, 2, 2, 3, 3, 3, 3, 4, 4, 4, 4, 4, 4, 5, 5, 5]
```

`pyphysim.util.misc.least_right_singular_vectors` (*A*: *numpy.ndarray*, *n*: *int*) → *Tuple*[*numpy.ndarray*, *numpy.ndarray*, *numpy.ndarray*]

Return the three matrices. The first one is formed by the *n* least significant right singular vectors of *A*, the second one is formed by the remaining right singular vectors of *A* and the third one has the singular values of the singular vectors of the second matrix (the most significant ones).

Parameters

- **A** (*np.ndarray*) – A 2D numpy array.
- **n** (*int*) – An integer between 0 and the number of columns of *A*.

Returns

The three matrices V0, V1 and S.

The matrix V0 has the right singular vectors corresponding to the *n* least significant singular values.

The matrix V1 has the remaining right singular vectors.

The matrix S has the singular values corresponding to the remaining singular vectors *V1*.

Return type `np.ndarray, np.ndarray, np.ndarray`

Notes

Because of the sort operation, if you call `least_right_singular_vectors(A, ncols_of_A)` you will get all the right singular vectors of *A* with the column order reversed.

Examples

```
>>> A = np.array([1,2,3,6,5,4,2,2,1])
>>> A.shape = (3,3)
>>> (min_Vs, remaining_Vs, S) = least_right_singular_vectors(A,1)
>>> min_Vs
array([[ -0.4474985 ],
       [  0.81116484 ],
       [ -0.3765059 ]])
>>> remaining_Vs
array([[ -0.62341491, -0.64116998 ],
       [  0.01889071, -0.5845124  ],
       [  0.78166296, -0.49723869 ]])
>>> S
array([1.88354706, 9.81370681])
```

`pyphysim.util.misc.leig` (*A*: *numpy.ndarray*, *n*: *int*) → *Tuple*[*numpy.ndarray*, *numpy.ndarray*]

Returns a matrix whose columns are the *n* least significant eigenvectors of *A* (eigenvectors corresponding to the *n* dominant eigenvalues).

Parameters

- **A** (*np.ndarray*) – A symmetric matrix (bi-dimensional numpy array)

- **n** (*int*) – Number of desired least significant eigenvectors.

Returns A list with two elements where the first element is a 2D numpy array with the desired eigenvectors, while the second element is a 1D numpy array with the corresponding eigenvalues.

Return type np.ndarray, np.ndarray

Notes

A must be a symmetric matrix so that its eigenvalues are real and positive.

Raises **ValueError** – If *n* is greater than the number of columns of *A*.

Examples

```
>>> A = np.random.randn(3,3) + 1j*np.random.randn(3,3)
>>> V, D = peig(A, 1)
```

pyphysim.util.misc.**level2bits** (*n: int*) → *int*

Calculates the number of bits needed to represent *n* different values.

Parameters **n** (*int*) – Number of different levels.

Returns **num_bits** – Number of bits required to represent *n* levels.

Return type *int*

Examples

```
>>> list(map(level2bits, range(1,20)))
[1, 1, 2, 2, 3, 3, 3, 3, 4, 4, 4, 4, 4, 4, 4, 4, 5, 5, 5]
```

pyphysim.util.misc.**peig** (*A: numpy.ndarray, n: int*) → *Tuple[numpy.ndarray, numpy.ndarray]*

Returns a matrix whose columns are the *n* dominant eigenvectors of *A* (eigenvectors corresponding to the *n* dominant eigenvalues).

Parameters

- **A** (*np.ndarray*) – A symmetric matrix (bi-dimensional numpy array).
- **n** (*int*) – Number of desired dominant eigenvectors.

Returns A list with two elements where the first element is a 2D numpy array with the desired eigenvectors, while the second element is a 1D numpy array with the corresponding eigenvalues.

Return type np.ndarray, np.ndarray

Notes

A must be a symmetric matrix so that its eigenvalues are real and positive.

Raises `ValueError` – If n is greater than the number of columns of A .

Examples

```
>>> A = np.random.randn(3,3) + 1j*np.random.randn(3,3)
>>> V, D = peig(A, 1)
```

`pyphysim.util.misc.pretty_time` (*time_in_seconds: float*) → *str*
Return the time in a more friendly way.

Parameters *time_in_seconds* (*float*) – Time in seconds.

Returns *time_string* – Pretty time representation as a string.

Return type *str*

Examples

```
>>> pretty_time(30)
'30.00s'
>>> pretty_time(76)
'1m:16s'
>>> pretty_time(4343)
'1h:12m:23s'
```

`pyphysim.util.misc.qfunc` (*x: float*) → *float*
Calculates the 'q' function of x .

Parameters *x* (*float*) – The value to apply the Q function.

Returns *result* – $Qfunc(x)$

Return type *float*

Examples

```
>>> qfunc(0.0)
0.5
>>> round(qfunc(1.0), 9)
0.158655254
>>> round(qfunc(3.0), 9)
0.001349898
```

`pyphysim.util.misc.randn_c` (**args: int*) → *numpy.ndarray*
Generates a random circularly complex gaussian matrix.

Parameters **args* (*any*) – Variable number of arguments (int values) specifying the dimensions of the returned array. This is directly passed to the `numpy.random.randn` function.

Returns *result* – A random N -dimensional numpy array (complex dtype) where the N is equal to the number of parameters passed to *randn_c*.

Return type *np.ndarray*

Examples

```
>>> a = randn_c(4,3)
>>> a.shape
(4, 3)
>>> a.dtype
dtype('complex128')
```

`pyphysim.util.misc.randn_c_RS` (*RS*: `numpy.random.mtrand.RandomState`, **args*: `int`) → `numpy.ndarray`

Generates a random circularly complex gaussian matrix.

This is essentially the same as the `randn_c` function. The only difference is that the `randn_c` function uses the global `RandomState` object in `numpy`, while `randn_c_RS` use the provided `RandomState` object. This allow us greater control.

Parameters

- **RS** (`np.random.RandomState`) – The `RandomState` object used to generate the random values.
- ***args** (*any*) – Variable number of arguments specifying the dimensions of the returned array. This is directly passed to the `numpy.random.randn` function.

Returns result – A random *N*-dimensional `numpy` array (complex dtype) where the *N* is equal to the number of parameters passed to `randn_c`.

Return type `np.ndarray`

`pyphysim.util.misc.replace_dict_values` (*name*: `str`, *dictionary*: `Dict[str, str]`, *filename_mode*: `bool = False`) → `str`

Perform the replacements in *name* with the value of `dictionary[name]`.

See the usage example below:

```
>>> name = "results_snr_{snr}_param_a_{param_a}"
>>> replacements = {'snr': np.array([0,5,10,15,20]), 'param_a': 'something'}
>>> replace_dict_values(name, replacements)
'results_snr_[0:5:20]_param_a_something'
```

Note that some small changes are performed in the dictionary prior to the replacement. More specifically, modifications such as changing a `numpy` array to a more compact representation (when possible). This is done by converting the `numpy` arrays with the `get_mixed_range_representation` function.

If the string is going to be used as a filename, pass `True` to *filename_mode* as in the example below

```
>>> replace_dict_values(name, replacements, True)
'results_snr_[0_(5)_20]_param_a_something'
```

Parameters

- **name** (`str`) – The name fo be formatted.
- **dictionary** (`dict`) – The dictionary with the values to be replaced in *name*.
- **filename_mode** (`bool`, *optional*) – Extra parameter passed to the `get_mixed_range_representation` function. If `True`, the returned representation will be more suitable to be used as part of a file-name. That is instead of “5:5:40” the string “5_(5)_40” would be used.

Returns new_name – The value of *name* after the replacements in *dictionary*.

Return type `str`

Examples

```
>>> name = "something {value1} - {value2} something else {value3}"
>>> dictionary = {'value1':'bla bla', 'value2':np.array([5, 10, 15, 20, 25, 30]), 'value3': 76}
>>> replace_dict_values(name, dictionary, True)
'something bla bla - [5_(5)_30] something else 76'
```

`pyphysim.util.misc.update_inv_sum_diag(invA: numpy.ndarray, diagonal: numpy.ndarray) → numpy.ndarray`

Calculates the inverse of a matrix $(A + D)$, where D is a diagonal matrix, given the inverse of A and the diagonal of D .

This calculation is performed using the Sherman-Morrison formula, given by

$$(A + uv^T)^{-1} = A^{-1} - \frac{A^{-1}uv^T A^{-1}}{1 + v^T A^{-1}u},$$

where u and v are vectors.

Parameters

- **invA** (`np.ndarray`) – A 2D numpy array.
- **diagonal** (`np.ndarray`) – A 1D numpy array with the elements in the diagonal of D .

Returns `new_inv` – The inverse of $A + D$.

Return type `np.ndarray`

`pyphysim.util.misc.xor(a: int, b: int) → int`

Calculates the xor operation between a and b .

In python this is performed with a^b . However, sage changed the “^” operator. This xor function was created so that it can be used in either sage or in regular python.

Parameters

- **a** (`int`) – First number.
- **b** (`int`) – Second number.

Returns The result of the *xor* operation between a and b .

Return type `int`

Examples

```
>>> xor(3, 7)
4
>>> xor(15, 6)
9
```

pyphysim.util.serialize module

Module containing function related to serialization.

class pyphysim.util.serialize.JsonSerializable

Bases: `object`

Base class for classes you want to be JSON serializable (convert to/from JSON).

You can call the methods `to_json` and `from_json` methods (the later is a staticmethod).

Note that a subclass must implement the `_to_dict` and `_from_dict` methods.

static `_from_dict` (*d*: Dict[str, Any]) → Any

Convert from a dictionary to an object.

Parameters *d* (*dict*) – The dictionary representing the object.

Returns The converted object.

Return type *Result*

`_to_dict` () → Dict[str, Any]

Convert the object to a dictionary representation.

Returns The dictionary representation of the object.

Return type *dict*

classmethod `from_dict` (*d*: Dict[str, Any]) → Any

Convert from a dictionary to an object.

Parameters *d* (*dict*) – The dictionary representing the Result.

Returns The converted object.

Return type *Result*

classmethod `from_json` (*data*: Any) → Any

Convert a JSON representation of the object to an actual object.

Parameters *data* (*str*) – The JSON representation of the object.

Returns The actual object

Return type *any*

`to_dict` () → Dict[str, Any]

Convert the object to a dictionary representation.

Returns The dictionary representation of the object.

Return type *dict*

`to_json` () → Any

Convert the object to JSON.

Returns JSON representation of the object.

Return type *str*

class pyphysim.util.serialize.NumpyOrSetEncoder (*, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None)

Bases: `json.encoder.JSONEncoder`

JSON encoder for numpy arrays.

Pass this class to `json.dumps` when converting a dictionary to json so that any field which with a numpy array as value will be properly converted.

This encoder will also handle numpy scalars and the native python set types.

When you need to convert the json representation back, use the `json_numpy_or_set_obj_hook` function.

See also:

`json_numpy_or_set_obj_hook`

default (*obj*: `Union[numpy.ndarray, numpy.int32, numpy.int64, numpy.float32, numpy.float64, numpy.float128, set]`) \rightarrow Any

If input object is an ndarray it will be converted into a dict holding data, dtype, `_is_numpy_array` and shape.

Parameters *obj* (*Serializable*) –

Returns

Return type Serialized Data

`pyphysim.util.serialize.json_numpy_or_set_obj_hook` (*dct*: `Dict[str, Any]`) \rightarrow
`Union[numpy.ndarray, numpy.int32, numpy.int64, numpy.float32, numpy.float64, numpy.float128, set]`

Decodes a previously encoded numpy array.

Parameters *dct* (*dict*) – The JSON encoded numpy array.

Returns The decoded numpy array or None if the encoded json data was not an encoded numpy array.

Return type `np.ndarray` | `set` | `dict`, optional

See also:

`NumpyOrSetEncoder()`

Module contents

Package with several utility modules and classes.

This includes the `SimulationRunner` class.

Module contents

The Pyphysim library provides many useful classes and functions to perform Monte Carlo simulations of communications systems.

1.2 Implementing Simulators with PyPhysim

Several simulators are already implemented in the “*apps*” package, and can be used as examples of how to implement simulators with the PyPhysim library. The best complete example is probably the “*apps/simulate_psk.py*” file.

In general, the *simulations* module provides a basic framework for implementing Monte Carlo Simulations and implementing a new simulator with PyPhysim starts by subclassing *SimulationRunner* and implementing the *SimulationRunner._run_simulation()* method with the code to simulate a single iteration for that specific simulator.

A few other classes in the *simulations* module complete the framework by handling simulation parameters and simulation results. The classes in the framework consist of

- *SimulationRunner*
- *SimulationParameters*
- *SimulationResults*
- *Result*

For a description of how to implement Monte Carlo simulations using the classes defined in the *simulations* module see *Implementing Monte Carlo simulations*.

1.2.1 Getting simulation Parameters from a file

Python has the *ConfigParser* library (renamed to *configparser* in Python 3) to parse configuration parameters. You can use it in the `__init__` method of your simulator class (the simulator main class that inherits from *SimulationRunner*) to read the simulation parameters from a file.

Another good alternative is using the *configobj* library, which provides an arguable easier to use API than *configparser*. Another advantage of using *configobj* is its ability to validate the configuration file.

1.3 Implementing Monte Carlo simulations

A Monte Carlo simulation involves performing the same simulation many times with random samples to calculate the statistical properties of some phenomenon.

The *SimulationRunner* class makes implementing Monte Carlo simulations easier by implementing much of the necessary code while leaving the specifics of each simulator to be implemented in a subclass.

In the simplest case, in order to implement a simulator one would subclass *SimulationRunner*, set the simulation parameters in the `__init__` method and implement the `_run_simulation()` method with the code to simulate a single iteration for that specific simulator. The simulation can then be performed by calling the *simulate()* method of an object of that derived class. After the simulation is finished, the ‘results’ parameter of that object will have the simulation results.

The process of implementing a simulator is described in more details in the following.

1.3.1 Simulation Parameters

The simulation parameters can be set in any way as long as they can be accessed in the `_run_simulation()` method. For parameters that won't be changed, a simple way that works is to store these parameters as attributes in the `__init__` method.

On the other hand, if you want to run multiple simulations, each one with different values for some of the simulation parameters then store these parameters in the `self.params` attribute and set them to be unpacked (See documentation of the `SimulationParameters` class for more details). The `simulate()` method will automatically get all possible combinations of parameters and perform a whole Monte Carlo simulation for each of them. The `simulate()` method will pass the 'current_parameters' (a `SimulationParameters` object) to `_run_simulation()` from where `_run_simulation()` can get the current combination of parameters.

If you want/need to save the simulation parameters for future reference, however, then you should store all the simulation parameters in the `self.params` attribute. This will allow you to call the method `SimulationParameters.save_to_pickled_file()` to save everything into a file. The simulation parameters can be recovered latter from this file by calling the static method `SimulationParameters.load_from_pickled_file()`.

1.3.2 Simulation Results

In the implementation of the `_run_simulation()` method in a subclass of `SimulationRunner` it is necessary to create an object of the `SimulationResults` class, add each desided result to it (using the `add_result()` method of the `SimulationResults` class) and then return this object at the end of `_run_simulation()`. Note that each result added to this `SimulationResults` object must itself be an object of the `Result` class.

After each run of the `_run_simulation()` method the returned `SimulationResults` object is merged with the `self.results` attribute from where the simulation results can be retrieved after the simulation finishes. Note that the way the results from each `_run_simulation()` run are merged together depend on the `update_type` attribute of the `Result` object.

Since you will have the complete simulation results in the `self.results` object you can easily save them to a file calling its `SimulationResults.save_to_file()` method.

Note: Call the `SimulationResults.set_parameters()` method to set the simulation parameters in the `self.results` object before calling its `save_to_file` method. This way you will have information about which simulation parameters were used to generate the results.

1.3.3 Number of iterations the `_run_simulation()` method is performed

The number of times the `_run_simulation()` method is performed for a given parameter combination depend on the `self.rep_max` attribute. It is set by default to '1' and therefore you should set it to the desired value in the `__init__` method of the `SimulationRunner` subclass.

1.3.4 Optional methods

A few methods can be implemented in the `SimulationRunner` subclass for extra functionalities. The most useful one is probably the `_keep_going()` method, which can speed up the simulation by avoid running unnecessary iterations of the `_run_simulation()` method.

Basically, after each iteration of the `_run_simulation()` method the `_keep_going()` method is called. If it returns `True` then more iterations of `_run_simulation()` will be performed until `_keep_going()` returns `False` or `rep_max` iterations are performed. When the `_keep_going()` method is called it receives a `SimulationResults` object with the cumulated results from all iterations so far, which it can then use to decide if the iterations should continue or not.

The other optional methods provide hooks to run code at specific points of the `simulate()` method. They are described briefly below:

- `SimulationRunner._on_simulate_start()`: This method is called once at the beginning of the simulate method.
- `SimulationRunner._on_simulate_finish()`: This method is called once at the end of the simulate method.
- `SimulationRunner._on_simulate_current_params_start()`: This method is called once for each combination of simulation parameters before any iteration of `_run_simulation` is performed.
- `SimulationRunner._on_simulate_current_params_finish()`: This method is called once for each combination of simulation parameters after all iteration of `_run_simulation` are performed.

At last, for a working example of a simulator, see the `apps/simulate_psk.py` file.

1.3.5 Example of Implementation

See the documentation of the `SimulationRunner` class for a pseudo implementation of a subclass of the `SimulationRunner`.

1.4 Running Simulations in Parallel

If some parameter was marked to be unpacked and instead of calling the `simulate()` method you call the `simulate_in_parallel()` method, then the simulations for the different parameters will be performed in parallel using the parallel capabilities of the IPython interpreter.

In order to call `simulate_in_parallel()` you need to first create a Client (`IPython.parallel.Client`) and then get a “view” from it. This view is a required argument to call `simulate_in_parallel()`.

The the IPython documentation to understand more.

1.5 Writing Documentation for PyPhysim

The handwritten rst files should be listed in the toctree in the *List of Documentation Articles* section of the `index.rst` file, while the documentation for each package is automatically generated using `sphinx-apidoc` and should be listed in the toctree in the `description.rst` file.

In order to generate the rst files for each package with `sphinx-apidoc` call the command `sphinx-apidoc -o docs pyphysim` from outside the docs folder.

Note that `sphinx-apidoc` will generate a corresponding `.rst` file for each package, that uses the `autodoc` feature of `sphinx` to include the docstrings of the python files in the actual documentation. For instance, the `.rst` file of the `comm` module (whose name is `pyphysim.comm.rst`) is shown below.

```
pyphysim.comm package
=====

Submodules
-----

pyphysim.comm.blockdiagonalization module
-----

.. automodule:: pyphysim.comm.blockdiagonalization
   :members:
   :undoc-members:
   :show-inheritance:

pyphysim.comm.waterfilling module
-----

.. automodule:: pyphysim.comm.waterfilling
   :members:
   :undoc-members:
   :show-inheritance:

Module contents
-----

.. automodule:: pyphysim.comm
   :members:
   :undoc-members:
   :show-inheritance:
```

Notice the use of “`.. automodule::`” to get the documentation of the `comm` package modules from the source code.

Therefore, you only need to run `sphinx-apidoc` when new modules are created in PyPhysim. Everything else will be automatically done by `sphinx` with the help of the `autodoc` extension.

1.5.1 Writing math in the documentation

The `sphinx` documentation generation system is configured to allow the inclusion of math snippets with LaTeX syntax in the documentation. Simply put a directive like `:math:`x+y = \frac{1}{2}`` in the documentation and it will be rendered as $x + y = \frac{1}{2}$ in the final HTML documentation.

In order for this to work you need to download MathJax from <http://www.mathjax.org/download/> and put it in the `docs/Mathjax/` folder.

Also, in order to make writing math easier, a few extra LaTeX macros should be defined. In special, we use bold to indicate matrices. Usually one would need to write `:math:`\mathbf{H}_{jk}`` to write \mathbf{H}_{jk} , but the macro “`\mtH`” is used instead for a bold “H” such that we can write the same thing with `:math:`\mtH_{jk}`` and this should be configured in Mathjax. Likewise, equivalent macros must also be defined for the other letters as well as `\vtH` and similar to represent vectors (lower case bold letters).

The after downloading Mathjax to the `docs/Mathjax/` edit the `docs/Mathjax/config/local/local.js` file and add the following macros there.

```

// Matrices
TEX.Macro("mtA", "\\mathbf{A}");
TEX.Macro("mtB", "\\mathbf{B}");
TEX.Macro("mtC", "\\mathbf{C}");
TEX.Macro("mtD", "\\mathbf{D}");
TEX.Macro("mtE", "\\mathbf{E}");
TEX.Macro("mtF", "\\mathbf{F}");
TEX.Macro("mtG", "\\mathbf{G}");
TEX.Macro("mtH", "\\mathbf{H}");
TEX.Macro("mtI", "\\mathbf{I}");
TEX.Macro("mtJ", "\\mathbf{J}");
TEX.Macro("mtK", "\\mathbf{K}");
TEX.Macro("mtL", "\\mathbf{L}");
TEX.Macro("mtM", "\\mathbf{M}");
TEX.Macro("mtN", "\\mathbf{N}");
TEX.Macro("mtO", "\\mathbf{O}");
TEX.Macro("mtP", "\\mathbf{P}");
TEX.Macro("mtQ", "\\mathbf{Q}");
TEX.Macro("mtR", "\\mathbf{R}");
TEX.Macro("mtS", "\\mathbf{S}");
TEX.Macro("mtT", "\\mathbf{T}");
TEX.Macro("mtU", "\\mathbf{U}");
TEX.Macro("mtV", "\\mathbf{V}");
TEX.Macro("mtW", "\\mathbf{W}");
TEX.Macro("mtX", "\\mathbf{X}");
TEX.Macro("mtY", "\\mathbf{Y}");
TEX.Macro("mtZ", "\\mathbf{Z}");

// Vectors
TEX.Macro("vtB", "\\mathbf{b}");
TEX.Macro("vtC", "\\mathbf{c}");
TEX.Macro("vtD", "\\mathbf{d}");
TEX.Macro("vtE", "\\mathbf{e}");
TEX.Macro("vtF", "\\mathbf{f}");
TEX.Macro("vtG", "\\mathbf{g}");
TEX.Macro("vtH", "\\mathbf{h}");
TEX.Macro("vtI", "\\mathbf{i}");
TEX.Macro("vtJ", "\\mathbf{j}");
TEX.Macro("vtK", "\\mathbf{k}");
TEX.Macro("vtL", "\\mathbf{l}");
TEX.Macro("vtM", "\\mathbf{m}");
TEX.Macro("vtN", "\\mathbf{n}");
TEX.Macro("vtO", "\\mathbf{o}");
TEX.Macro("vtP", "\\mathbf{p}");
TEX.Macro("vtQ", "\\mathbf{q}");

1.6 Writing Unittests for PyPhysim

The standard `unittest` module is used to implement automated tests for the several packages in the PyPhysim library. The tests are located in the `tests` folder, which should contain a single test file for each package in PyPhysim.

Each test file contains several *test case* classes, as usual in the unittests framework. The first test case class is always a *Doctests test case*, that is, a test case that simple run all the doctests in each module of the package.

After that, a test case class must be implemented for each module in the package, which in turn should test all the classes and functions in that module.

1.6.1 Test Coverage

Ideally unittests should be implemented at the same time the actual code is implemented (or even before that). However, sometimes the tests are implemented the tested code and this may leave code untested.

A good way to make sure that we have a good test coverage in PyPhysim is using the *python-coverage* program. With it we can run all the implemented unittests and get a report of the lines in any module in PyPhysim that was not run by any unittest (thus finding untested code). The *bin* folder contains a script called `run_python_coverage.sh` that will do exactly that.

1.6.2 Code Quality

A good way to ensure code quality, besides implementing unittests, is to employ code analisys tools such as pylint, pep8, pychecker, etc.

For the quality of PyPhysim as a package, see the `cheesecake_index` tool.

- <http://pycheesecake.org/>
- <http://infinitemonkeycorps.net/docs/pph/>

Notes

If you use pylint, this is the `.pylintrc` file I use (although I don't struggle to fix every pylint warning)

```
[MASTER]

# Specify a configuration file.
#rcfile=

# Python code to execute, usually for sys.path manipulation such as
# pygtk.require().
init-hook='import sys; sys.path.append("./"); sys.path.append("../")'

# Profiled execution.
profile=no

# Add files or directories to the blacklist. They should be base names, not
# paths.
ignore=CVS

# Pickle collected data for later comparisons.
persistent=yes
```

1.7 Speeding up PyPhysim

A famous Donald Knuth statements is that “premature optimization is the root of all evil”. Before even thinking about optimizing some python code that code should be fully tested with unittests. (see *Writing Unittests for PyPhysim*).

With properly tested code, if the current speed is not enough the first step is to profile the code to identify bottlenecks. The following section describes how to profile code in python.

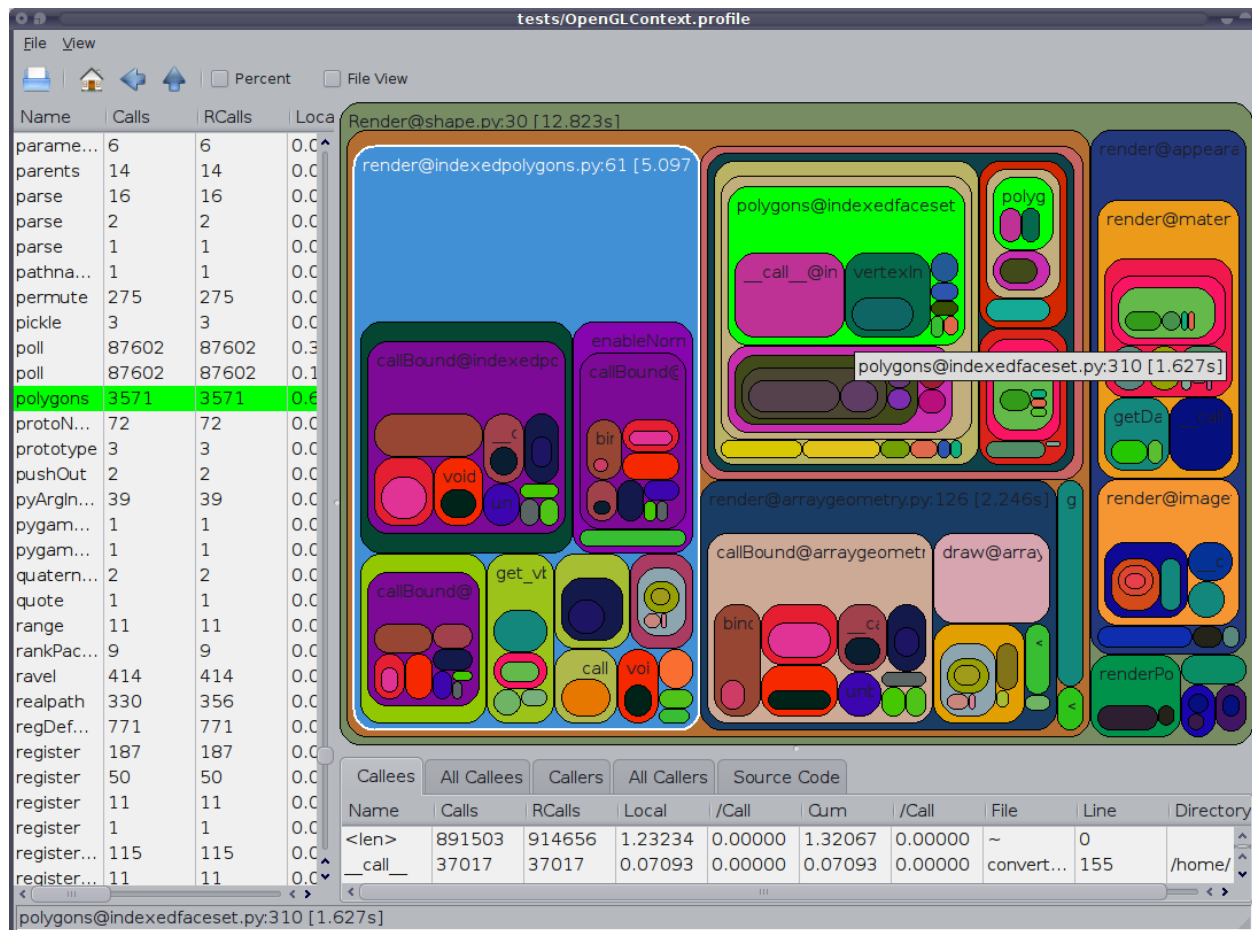

1.7.1 Profiling the Code

There are multiple ways to profile python code and visualize the profile output. An easy way is to use the `%run` command in the ipython interpreter with the `-p` option to run a python script with the python profiler and present the results after the script finishes.

If you prefer to graphically visualize the profile data you can use the `runsnakerun` program. In order to use it, first you need to run the script using the `cProfile` module to generate the profile data and then you can visualize the profile data with the `runsnakerun` program. That is

```
$ python -m cProfile -o <outputfilename> <script-name> <options>
$ runsnake <outputfilename>
```

Here is an image (from <http://www.vrplumber.com/programming/runsnakerun/>) showing runsnakerun in action.

After identifying which parts in the code need to be optimized, there are multiple ways to achieve faster speeds in python. In PyPhysim we use Cython for that, as described in the following section.

Line Profiler

Another option for profiling is use the line_profiler module. Install the module with

```
$ sudo pip install line_profiler
```

With this the script kernprof.py is also installed. Now, decorate the function you want to profile and run a script that calls the function through kernprof with

```
$ kernprof.py -l -v my_script.py
```

See mode in http://pythonhosted.org/line_profiler/

Memory Profiler

See the blog post below for a way to profile the memory usage of your program. <http://www.huyng.com/posts/python-performance-analysis/>

1.7.2 Implementing parts of PyPhysim in Cython

Some tutorials about using Cython can be found in - <http://docs.cython.org/src/userguide/tutorial.html> - <http://wiki.cython.org/tutorials/numpy> - <http://docs.cython.org/src/tutorial/index.html> - <http://blog.perrygeo.net/2008/04/19/a-quick-cython-introduction/> - http://scipy-lectures.github.com/advanced/advanced_numpy/index.html#exercise-building-an-ufunc-from-scratch - <http://wiki.cython.org/PackageHierarchy>

The setup.py and setup.cfg files are already properly configured to compile the Cython extensions implement in PyPhysim. Simple call the command

```
$ python setup.py build_ext
```

to compile all the Cython extensions.

In order to describe how the Cython extensions are implemented in PyPhysim lets use the *count_bits* function in the *util.misc* module as an example. We want to make it faster by re-implementing it in Cython.

First the *.count_bits* function was implemented in pure python in *util.misc* and properly tested in the *util_package_test.py* file along the other functions in *util.misc*.

After that the file *misc_c.pyx* was created, which contains the implementation of *.count_bits* in Cython. Note that the name is equal to the name of the module where the *.count_bits* function originally lives with an added *_c* and the *pyx* extension. The re-implementation in Cython of any function in *util.misc* should be in *misc_c.pyx*.

Then setup.py should be modified to create an extension from the *misc_c.pyx* file (and any other source file it depends on). In the *misc_c.pyx* case this corresponds to adding the code below to setup.py

```
misc_c = Extension(name="misc_c", sources=["util/misc_c.pyx"],
                  include_dirs=[numpy.get_include()])
```

and adding “misc_c” to the ‘ext_modules’ list (an argument of the setup function in the setup.py file).

At last, we add code to the *util.misc* module to use the functions defined in *misc_c.pyx* so that for someone using importing the *util.misc* module it is transparent if the functions are implemented there (in python) or in *misc_c.pyx*. This can be easily done by putting the code below at the end of the *misc.py* file.

```
# xxxxxx Load Cython reimplementatoin of functions here xxxxxxxxxxxxxxxxxxxxxxxx
try:
    # If the misc_c.so extension was compiled then any method defined there
    # will replace the corresponding method defined here.
    from c_extensions.misc_c import *
except Exception:
    pass
# xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```

The idea is that the user should never import the compiled Cython extension, but only *util.misc*. The code above is enough to replace any functions defined in *misc.py* by the equivalent function defined in *misc_c.pyx* whenever the Cython extension is compiled, or use the native python version when the Cython extension is not compiled.

Note: The setup.cfg file is configured so that all the compiled Cython extensions are put in the *c_extensions* folder.

This method has the added benefit that we can run all the unittests on the pure python versions, then compile the Cython extensions and run the unittests again to test the Cython extensions.

Profiling Cython Code

See http://docs.cython.org/src/tutorial/profiling_tutorial.html

You can enable profiling for a Cython source file by putting

```
# cython: profile=True
```

in that source file.

Todo: Verify if this is really necessary when the code is compiled into an extension of only if we had used the `pyximport`.

Once enabled, your Cython code will behave just like Python code when called from the `cProfile` module. This means you can just profile your Cython code together with your Python code using the same tools as for Python code alone.

Note: If your profiling is messed up because of the call overhead to some small functions that you rather do not want to see in your profile - either because you plan to inline them anyway or because you are sure that you can't make them any faster - you can use a special decorator to disable profiling for one function only:

```
cimport cython

@cython.profile(False)
def my_often_called_function():
    pass
```

This is important because once `my_often_called_function` is optimized enough you might want to optimize its calling function and the overhead from profiling `my_often_called_function` not added to `my_often_called_function` but to its calling function. Therefore, disabling profiling for `my_often_called_function` will give you more reliable information when optimizing its calling function.

1.7.3 Other Alternatives to speed-up python code

There are a number of alternatives to speed-up python code.

- you can use the `weave` module (inline or `blitz` methods) from `scipy` to speed up things here. See <http://docs.scipy.org/doc/scipy/reference/tutorial/weave.html> and <http://www.scipy.org/PerformancePython>
- You could use Cython
- You could try `numexpr` <http://code.google.com/p/numexpr/>
- You could try `Numba` <http://jakevdp.github.com/blog/2012/08/24/numba-vs-cython/>
- Use smart numpy broadcast tricks to avoid loops This is fast, but uses more memory. See the source code of the `Modulator.demodulate()` method.
- General tips <http://scipy-lectures.github.com/advanced/optimizing/index.html#line-profiler>

1.8 Packaging

We use virtualenv and pip.

In the main folder, create an environment with

```
$ virtualenv env
```

This will create a `env` folder. Activate the environment with

```
$ source env/bin/activate
```

Now you can install the python dependencies such as numpy, scipy, Cython, IPython, etc.

1.9 Typing Support in PyPhysim

PyPhysim has an increasing support for static typing checking.

Ideally everything in PyPhysim should be type checked without errors by `mypy` and any new code should ideally have typing information as well.

Note: There are other type checkers that can be used, such as `pytype` (from Google) or `pyre` (from Facebook)

1.9.1 Some useful information:

- [What is the difference between TypeVar and NewType?](#)
- [Covariance, Contravariance, and Invariance — The Ultimate Python Guide](#)
- [Python Type Checking \(Guide\)](#)
- Accepting any derived class: If the number of subclasses is fixed, just create a Union with all of them. If it is not and you truly want “any subclass of Base”, then try “`Generic[Base]`” as the argument type.

```
FadingGenerator = TypeVar('FadingGenerator',
                           bound=FadingSampleGenerator)
```

- Inspecting the type of variables: Use `reveal_type(expr)` to see the type of `expr`. It only works in `mypy` and you get a `NameError` if you try to run code with it in Python.
